Controversy has surrounded some selections, as the committee has tried to balance between complying with Nobel’s will and using the prize to promote Norwegian interests and values. The awarding of the 1906 Peace Prize to Theodore Roosevelt is one early example of this balance. Roosevelt was the first head of state to be so honored. While the prize was given because of his involvement in the mediation of the Japanese-Russian war, the former Rough Rider enjoyed a rather bellicose reputation. Nevertheless, Roosevelt was chosen in part because Norway, which had just received its independence from Sweden in 1905, was, as one Norwegian newspaper put it, in need of a “large, friendly neighbor.” In addition, the prize signaled the willingness of the committee to at times award prizes based on specific actions rather than the overall “peacefulness” of the person in question. Prizes to such figures as Henry Kissinger and Le Duc Tho (1973), Yasir Arafat (1994), and Anwar Sadat and Menachem Begin (1978) similarly reflect this tendency.

The Nobel Committee has also used the prize to punish, rather than reward, behavior. For example, the 1935 prize was given to Carl von Ossietzky, a German journalist and dissident who wrote scathing articles against the Nazi Party for which he was sent to a German concentration camp. The prize was given to Ossietzky as much to condemn German behavior as it was to honor Ossietzky. Other cases in which the committee has used the prize to highlight atrocities being carried out by specific governments include Shirin Ebadi of Iran in 2003, Carlos Filipe Ximenes Belo and Jose Ramos-Horta of East Timor in 1996, Aung San Suu Kyi of Myanmar (Burma) in 1991, Desmond Tutu of South Africa in 1984, Lech Walesa in 1983, Martin Luther King Jr. of the United States in 1964, and Albert Lutuli of South Africa in 1960.

NODE, STABLE
If all the paths of equilibrium noncyclically converge to it, the equilibrium is a stable node. The conditions for the equilibrium to be a stable node are a function of the system being evaluated, in particular, whether the issue of concern involves discrete versus continuous change or is a linear versus nonlinear system. If the dynamic system is discrete and linear,

\[ \dot{y} = ay + b \]

The equilibrium is stable if and only if \( a > 0 \).

For continuous linear dynamic systems, an equilibrium is defined as a stable node if the slope of the differential equation in the neighborhood of the equilibrium is negative. For nonlinear discrete or continuous dynamic systems, the Taylor expansion about \( x^*_i \), a nonzero equilibrium, must satisfy the following for \( x^*_i \) to be stable: \( |f'(x^*_i)| < 1 \). The concept of a stable node can be extended to simultaneous systems of discrete or continuous equations. The condition for a stable node is the same for discrete and continuous simultaneous systems of equation. If \( |\lambda| < 0 \), where \( \lambda \) are the eigenvalues that solve equation, then \( \lambda \) is stable. If the eigenvalues are complex, the real part must be negative for the eigenvalues to be stable.

The concept of a stable node is used to describe the dynamics of (1) an oligopoly—stability of a Cournot solution; (2) the IS-LM—stability after monetary and/or fiscal shocks; (3) the model of inflation and unemployment—stability of fiscal or employment policies; and (4) population models—stability of growth. The characterization of a node as stable is most useful in the qualitative analysis of differential equations using phase diagrams, which describes the paths of a system in and out of equilibrium.

Nominal Income

Many societies strive to improve the well-being of their members by increasing incomes. The statement “Canadian household incomes have increased,” may give an immediate impression that these households are better off. However, this may not necessarily be the case if nominal income is considered because inflation may completely erode any nominal income gains.

Nominal income is income that is not adjusted for changes in purchasing power, the amount of goods or services that one can afford with the income, owing to inflation. Adjusting nominal income for inflation is important because inflation decreases the amount of goods or services that one can afford with a given amount of nominal income. To see how inflation can erode nominal income gains, suppose that nominal income rises by 50 percent this year over last year. An individual is, in fact, better (worse) off if prices rise by less (more) than 50 percent over the same period, since the amount of goods or services that person can afford with the higher nominal income is more (less). Since nominal income is not adjusted for changes in the cost of living due to inflation, it is not a fully satisfactory measure of well-being. Fortunately, nominal incomes (e.g., wages, pensions) can be successfully adjusted to avoid loss in purchasing power due to inflation, provided that inflation is correctly anticipated.

Problems may arise when making international comparisons of nominal incomes. Suppose that the nominal income of a U.S. resident rises by $1 and that of a Ugandan resident also rises by the same amount. If the amount of goods or services that one can afford with the $1 is higher in Uganda than in the United States, then the $1 received in Uganda should be considered to be the higher income. Therefore, for international comparisons of nominal incomes (and other variables expressed in monetary terms), adjustments for purchasing power differences among countries are necessary. It is therefore not surprising that, for poverty comparison purposes, the World Bank (2005) reports the percentage of the population living on less than $1 a day after adjusting for purchasing power parity (PPP).

Even if nominal income is successfully adjusted for inflation (or PPP), some philosophical issues exist surrounding the appropriateness of nominal income as a measure of well-being. For example, according to the Capabilities Approach attributed to Amartya Sen, winner of the 1998 Nobel Prize in economics, functional capabilities (i.e., what a person can do or can be) are more important than income improvements.

The concept of nominal income is also commonly used in national income accounting to refer to nominal gross domestic product (GDP), the nominal value of all goods and services produced within a country’s borders during a given time period. In evaluating nominal GDP, the output for a given year is evaluated using that year’s prices. The practice of using nominal income to refer to nominal GDP is reflected in the vast literature on nominal income targeting, including the work of Henrik Jensen.

Nominal Wages

more with them. When nominal wages increase less than do price levels, recipients can buy less with them.

Classical economists believed that economic behavior is rational in the sense that it responds to real rather than nominal values. In labor markets, this implies that workers interpret a given decrease in real wages identically whether it was caused by a rise in inflation or by a fall in nominal wages. One of the key departures of John Maynard Keynes in his *General Theory of Employment, Interest, and Money* (1936) was that “a situation where labour stipulates (within limits) for a money-wage rather than a real wage, so far from being a mere possibility, is the normal case. Whilst workers will usually resist a reduction of money-wages, it is not their practice to withdraw their labour whenever there is a rise in the price of wage-goods” (p. 9). Nominal wages matter because nominal cuts typically occur in piecemeal fashion, which, in turn, alters any single group of workers’ relative wage position. Thus, resistance to nominal wage cuts is a defense of one’s relative wage position. If money wages could be lowered universally by the same percentage, Keynes’s analysis suggests that there would be no more resistance on the part of labor than to the effects of a general inflation.

Early evidence of the downward nominal wage rigidity, or “sticky wages,” was found in observed macroeconomic relationships. Increasing real wages during the Great Depression was attributed to falling prices combined with downward nominal wage rigidity. The post–World War II Phillips curve—the negative relationship between nominal wage changes and unemployment rates—was also explained by sticky wages, as was the non-neutrality of money supply, whereby money supply cuts caused recessions. Later studies have countered this “evidence” with alternative explanations—not based on nominal wages—that predict the same relationships.

Beginning in the 1980s, evidence of downward nominal wage rigidity has been sought in the time patterns of wages of individual workers within companies. This research has found many people with exactly zero nominal wage changes and very few whose nominal wages decrease, in contrast to no workers with exactly zero real wage changes and many whose real wages decrease. This holds true for low and moderate inflationary environments.

Different theoretical explanations of downward nominal wage rigidity assume different amounts of worker rationality. Many economists model nominal wage rigidities as rational responses to unanticipated shocks combined with imperfect information or costly wage changes. For instance, if workers can observe their own wage increases or decreases but not others’ wages and not general inflation levels, they may temporarily erroneously interpret a nominal wage cut as a negative signal (of the match quality or of the company’s health) rather than a response to an economy-wide decline. It may take time for firms to be certain that their economic situations warrant wage responses, particularly when information arrives intermittently. Both time and administrative costs may be required to both gather the relevant information and implement changes in nominal pay levels, leading to infrequent, staggered wage adjustments. Any of these factors can have major macroeconomic implications. Many theories predict these implications to last only for a short run, although some models imply pervasive stickiness.

Downward wage rigidities have also been attributed to efficiency wages—that is, paying higher than market-clearing wages to increase productivity or worker quality—or to insider-outsider theories—where insider workers have bargaining power within firms. However, both of these explanations generate real rather than nominal rigidities, unless coupled with misperceptions or costly adjustments.

An intermediate view assumes “near-rationality.” Humans have finite cognitive capacity and must edit out minor factors by using simple, unvarying rules of thumb. In environments of low inflation, individuals bear few costs if they assume that prices and nominal wage structures are constant. If many workers and/or firms behave in this way, however, it creates slowdowns that can persist.

Other psychologically based explanations emphasize that workers often infuse their nominal (money) wages with independent psychological meanings. Opinion surveys and experimental evidence have shown that many people’s self-esteem or sense of self-worth depends on the level and changes of their nominal wages, particularly in comparison to the nominal wages of others within their firm. Many workers believe it unfair if employers violate social norms by decreasing nominal wages, even in response to a weak labor market. Finally, individuals have been shown to place more weight on achieving losses than achieving gains. In this context, decreases in nominal wages lower morale, which can lead to reduced productivity and/or turnover. Given this, rational employers are reluctant to lower nominal wages, preferring to let real wages fall as prices rise.

NON-ALIGNMENT

Non-alignment is a philosophy for the conduct of international relations that was introduced into the diplomatic and scholarly vocabulary in 1961 with the founding of the Non-Aligned Movement (NAM). It was a product of the cold war, and its founders declared that they would not be aligned to either of the two competing political camps, led by the United States and the Soviet Union. The key intellectuals of Non-alignment philosophy have been Josip Tito, Fidel Castro, Julius Nyerere, Jawaharlal Nehru, Amilcar Cabral, and Léopold Senghor. The two central ideas of Non-alignment are the freedom to conduct an independent foreign policy and the eschewing of alliance politics. However, because the leading states of the NAM during its early years—such as Cuba and Yugoslavia—were closer to the USSR than to the United States, the movement has had the reputation of not promoting independent foreign policies. It has not been taken seriously in the academic power centers of international relations in North America and Europe. However, the NAM has been one of the most durable mechanisms of rhetorical mobilization for most of the former colonies of the world, and particularly powerful at the United Nations General Assembly, where the nonaligned bloc has been able to put on the agenda initiatives that the great powers would rather not debate, including, most prominently, proposals for a New International Economic Order and a New World Information and Communication Order.

It is useful to see Non-alignment as one of a variety of political strategies used by states to pursue their interests and survive in international politics. In contrast, the “power politics” strategy deployed by the most powerful states in the international system involves promoting alliances and placing military concerns ahead of economic and social development as objectives of foreign policy. In its early years (1961–1971), Non-alignment was seen as a form of neutrality, a philosophy of foreign policy conduct that eschewed international alliances of all types, even membership in the United Nations. However, the death knell of formal neutrality came with Switzerland’s joining the United Nations in 2002. In contrast, Non-alignment has been durable, and its use of UN structures to pursue the collective foreign policy aims of its members is evidence of its attractiveness and viability as a “third way” of international relations. However, it is important to note that Non-alignment is not a revolutionary philosophy in international politics, because it adheres to the principle that the state is the primary actor in international affairs and it promotes the continued viability of the United Nations. The so-called “cultural turn” in international relations may mean that Non-alignment will be increasingly studied for its insights into identity construction in international politics.

NONBLACKS

Although racial and ethnic minority groups in the United States have been afforded many opportunities, they have also experienced a great deal of oppression over the course of U.S. history. Native Americans lost thousands of acres of land to early American settlers, and a large percentage of the Native population died in the process. In the mid-to late 1800s, individuals of Chinese descent were welcomed to the country to help build railroads, only to be excluded from citizenship and naturalization once the task was completed. Thousands of innocent Japanese-Americans were interned in the name of national security following the bombing of Pearl Harbor, resulting in the loss of billions of dollars worth of land and personal property. Blacks in America suffered the peculiar institution of slavery, the failure of reconstruction, and the insults and violence of Jim Crow. They also endured violence and bloodshed during the fight for civil rights, and they continue to address the backlash against affirmative action. Hispanics, likewise, have faced discrimination. They have been exploited for their labor and marginalized based upon their race, country of origin, and the continued use of their native tongue. Collectively, these groups are referred to as nonwhites.

Whites in America are the dominant racial group, and as such have historically had greater access to property, power and prestige than other racial groups. There have
Noncompeting Groups

historically been large socioeconomic differences between whites and nonwhites, particularly in regard to wealth, income, educational attainment, and occupational opportunity and prestige. These differences have been most apparent between whites and blacks. Variations have also been observed between blacks and other racial and ethnic minority groups, and there has been an emergence of a “black” versus “nonblack” dichotomy. There are political as well as methodological implications for this distinction.

The designation “black” is used to describe a group of individuals that share not only similar phenotypical characteristics, such as skin color. Even more significantly, those labeled “black” are similar in that they are likely to receive unequal treatment compared to whites. The classification of “black” and “nonblack” persons is problematic, however, because the latter term often includes groups that may not be identified as black but have nonetheless had experiences comparable to that of blacks in terms of social and economic injustice. Cubans, Puerto Ricans, and Dominicans, for example, have suffered discrimination and unequal treatment in many arenas.

Moreover, the use of these terms to refer to various groups in quantitative analyses may provide support for the belief held by some about the inherent pathology of black culture, while also helping to mask the role of structural barriers in limiting upward social mobility among blacks and other minority groups. Instead of addressing the structural barriers that contribute to observed black-white disparities, efforts to eliminate the “black” category have emerged.

Some have questioned the usefulness of the black-nonblack dichotomy, given the successes of the multiracial movement in the late twentieth century. In 2000, for example, the U.S. Census Bureau allowed individuals to identify with more than one race. The use of this dichotomy is also deemed by some to have little use politically, given what can be described as the “Latin Americanization” of American racial norms. American society, in other words, can be seen as moving from a bira-cial classification system to a more complex multiracial or multicultural classification system. But the political successes associated with the multiracial movement do not render the black-nonblack dichotomy, or other racial classification scheme, empty. Instead, they highlight the fact that such classifications are multilevel and multidimensional—and often politically contested.

NONCOMPETING GROUPS

The concept of noncompeting groups—labor that is sheltered from market competition—has a controversial history that parallels the evolution of labor markets during industrialization. Since the mid-nineteenth century, non-competing groups have been variously defined in terms of occupation, social class, unionization, gender, race, and economic disadvantage. More recently, the microeconomic foundations of noncompeting groups have also been a topic of study.

NONCOMPETING GROUPS AND INDUSTRIALIZATION

Noncompeting groups were largely peripheral to labor market analysis at the time of the Industrial Revolution. Adam Smith (1723–1790), for example, emphasized the importance of “a competition among masters, who bid against one another in order to get workmen” when labor demand is growing and among workers who “bid against one another” when labor supply exceeds demand (Smith [1776] 1937, bk. 1, chap. 8, p. 71).

It was the Irish economist J. E. Cairnes (1823–1875) who coined the term noncompeting groups as applied to broad occupational categories—artisans and small retailers, highly skilled producers, and professionals (Cairnes 1874, p. 68). Cairnes saw entry into these groups as limited by law and custom, nontransferable skills, and the constraints of poverty (p. 62). Foreshadowing subsequent analysis of noncompeting groups by social class and race, John Stuart Mill (1806–1873) perceived these barriers as “so complete … as to be almost equivalent to a hereditary
distinction of caste” (Mill [1848] 1909, vol. 1, bk. 2, chap. 14, p. 480), but he also saw education and training as a source of intergenerational mobility between “grades” of labor provided that rules of social custom could be relaxed.

The turn of the century, however, lessened the importance of noncompeting groups (Fishback 1998), and English economist Alfred Marshall (1842–1924) saw technological change and the growth of mass production as reducing skill barriers to mobility and favoring transferable workforce attributes such as “sagacity and energy” and the ability “to accommodate oneself quickly to changes in detail of the work to be done” (Marshall [1890] 1930, bk. 4, chap. 6, secs. 2–3).

THE REEMERGENCE OF NONCOMPETING GROUPS

The growth of unions after World War II (1939–1945) focused attention on the role of labor market institutions, such as unions, in contributing to noncompetitive elements in labor markets and wage determinations (Dunlop 1958; Lewis 1986; Hirsch and Addison 1986). At the microlevel, these distinctions translated into the “balkanization” of labor markets (Kerr 1954) and a “new industrial feudalism” (Ross 1958). At the macroeconomic level, entry into occupations was sometimes controlled by unions and licensure, hiring by firms was limited to entry jobs, and wage-setting was insulated from competitive forces by entry barriers and bargaining power (Reynolds 1951).

As unions and collective bargaining diminished and new social concerns emerged during the 1960s and 1970s, barriers to employment affecting “noncompeting” groups defined by gender, race, and class began to receive attention. Theories of discrimination reflecting segregated labor markets were developed (Becker 1957; Arrow 1972); persistent earnings differentials by race, gender, and class were identified (Blau and Kahn 2000; Cain 1987); and there was renewed interest in “dual economy” models of labor market segmentation (Lewis 1979; Doeringer and Piore 1971; Gordon, Edwards, and Reich 1982; Darity and Mason 1998). However, the importance of these noncompetitive elements in labor markets remains controversial (Cain 1976; Wachter 1974; Dickens and Lang 1993; Gordon, Edwards, and Reich 1982).

THE MICROFOUNDATIONS OF NONCOMPETING GROUPS

A parallel stream of analysis exploring the microeconomics of noncompeting groups has also flourished since the 1960s. Economists extended the 1950s research on employment practices within firms by developing the concept of internal labor markets in which long-term employment matches were formed that favored “internal” over “external” labor mobility (Doeringer and Piore 1971; Williamson, Wachter, and Harris 1975).

The legacy of this research on internal labor markets as noncompeting groups is a new focus on organizational efficiency as a response to various failures of competitive labor markets—firm-specific skills, poor information on the productive qualities of workers and the adverse aspects of jobs, principle-agent conflicts arising from difficulties in monitoring worker productivity, and the difficulty in writing employment contracts that could fully anticipate future contingencies. This approach was initially articulated in Oliver Williamson’s Markets and Hierarchies (1975) and has been refined under the rubric of the “personnel economics” (Lazear 1999).

In this new incarnation, the limited entry, job hierarchies, and wage premiums found in internal labor markets were seen as improving the efficiency of imperfect external labor markets. Firm-specific skills led employers to offer efficiency wages (pay premiums above market rates for productive worker attributes) and promotions as incentives to reduce quits among trained workers; the threat of discharge from high-wage career jobs provided incentives for motivating productivity and reducing shirking; and implicit contracts providing high wages and secure employment markets were an efficient response to economic uncertainty (Katz and Summers 1989; Lang, Leonard, and Lilien 1987).

IMPLICATIONS FOR INEQUALITY AND ECONOMIC PERFORMANCE

Early theories emphasized the market distortions caused by noncompeting groups, as did subsequent work on labor markets segmented by unions, race, gender, class, and the employment practices of firms, as did much of the postwar research on the microfoundations of competing groups. In contrast, the new microeconomics of internal labor markets has tended to focus on the role of organizational efficiency in improving the economic performance of firms, and a large literature is emerging on the productivity gains to be made from sharing these efficiency gains with workers through higher wages, promotion opportunities, and participation in management decisions (Doeringer, Terkla, and Evan-Klock 2002, chap. 1).

The institutions of organizational efficiency, however, can also contribute to the ability of noncompeting groups within firms to increase their share of these gains in ways that may have adverse consequences. For example, firm-specific investments in training and labor market information, as well as unionization, can endow “insiders” with bargaining power that can be used to raise wages and limit job access by “outsiders” (Solow 1985). High wages can contribute to unemployment (Yellen 1984), and can also result in large pools of job applicants that make it easier to
Noncompeting Groups

use race and class as exclusionary hiring criteria, while job ladders that provide efficient training can also become barriers to internal mobility by gender and race (Osterman 1979). In effect, noncompeting efficient internal labor markets can be both sources of productivity growth and enclaves of empowered insiders.

NONCOOPERATIVE GAMES

Strategic games model conflict and cooperation, with the payoff to any player depending on the choice of strategy (a rule for selecting an action given each possible information set) not only by that player, but by all players. Strategic games can either be cooperative games, where some external authority exists that could enforce an agreement among the players, or noncooperative games, where no such external enforcement of agreements is available. Only self-enforcing agreements are possible in noncooperative games. Because binding agreements cannot be made, players in a noncooperative game may end up in a Pareto-inferior outcome, as in prisoner’s dilemma (q.v.), because a strategy combination that would produce a better outcome for all players would leave at least one player with an incentive to deviate. Most game theory emphasizes noncooperative games, because there is no consensus about how to choose among the various solution concepts proposed for cooperative games (such as the core, kernel, nucleolus, and Shapley value). Noncooperative game theory builds primarily upon refinements of one solution concept, Nash equilibrium.

A Nash equilibrium is a strategy combination for which no player has an incentive to be the only player to switch to another strategy. John Nash, in articles from 1950 and 1951 and his 1996 volume of essays, proved that any strategic game with a finite strategy space and arbitrarily many players will have at least one equilibrium point, provided that players are allowed to choose mixed strategies (strategies that assign probabilities to the possible pure strategies, so that a player’s action at a particular decision node cannot be predicted with certainty). Nash equilibrium has been interpreted as a generalization of A. Cournot’s analysis of duopoly in 1838, where each of two mineral water suppliers chooses its profit-maximizing output as a best response to the other’s output, taking the other firm’s quantity as given, and equilibrium occurs where their reaction functions intersect and neither firm can profit by being the only one to change its quantity produced. However, Robert Leonard, in his 1994 article, suggests that this view reads too much into Cournot. The minimax mixed-strategy solution for two-person zero-sum games, whose existence was proved by John von Neumann in 1928, is a special case of Nash equilibrium for n-person, general sum games. Nash equilibrium need not be unique, and so refinements have been introduced to eliminate as unreasonable some of the Nash equilibria in a game with multiple equilibria, such as considering as reasonable only those Nash equilibria that are subgame perfect. A subgame perfect Nash equilibrium is a strategy combination that would still be a Nash equilibrium if the game was started at any decision node (even one that would never be reached in equilibrium), so that players make only credible threats (that is, a player does not adopt a strategy implying that, if he or she were ever to be at particular off-equilibrium point, the player would do something that would decrease the player’s expected payoff).

For a game with multiple subgame perfect Nash equilibria, the concept of trembling hand equilibrium, where a player attaches a small probability to another player making a mistake, permits further restriction of the equilibria admitted as reasonable.

Because a Nash equilibrium is self-enforcing (no player can gain from being the only one to deviate), it is widely accepted as a plausible solution concept when there is preplay communication among players (especially if the Nash equilibrium is unique). As David G. Pearce’s 1984 article argues, if players cannot talk, or cannot reach agreement on which of multiple Nash equilibria to select, other strategy combinations that are Nash equilibria may be rationalizable. A strategy is rationalizable if there exists a consistent set of beliefs about the strategies and beliefs of all the other players for which that strategy is optimal, with each player maximizing his or her expected payoff subject to his or her subjective beliefs. However, rationalizability greatly extends the range of admissible solution concepts (as the possibility of binding agreement does for cooperative games), so that players, and game theorists analyzing the games they play, may fall back on Nash equilibrium as a focal point. Nash equilibrium, together with its refinements (especially subgame perfection in multistage games), remains the workhorse of noncooperative game theory, which in turn is the most developed and most widely influential form of game theory, spreading across disciplinary boundaries.

Nondecision-making

Peter Bachrach and Morton Baratz (1970) first introduced the concept of nondecision-making, contesting the dominant explanation of the use of power in decision-making by asking how issues are suppressed and the scope of decision-making restricted. This was a challenge to Robert Dahl’s conceptualization of power, which tended to focus on how decisions are made. Bachrach and Baratz suggested that to fully understand power, researchers should also consider decisions that are not made—nondecisions. Nondecision-making involves suppressing challenges to the status quo and suppressing the addition of new issues to an agenda. Issues are excluded from an agenda because they are threatening in some direct way, or because of the competition for the limited space for agenda items.

The concept of nondecision-making is best understood in relation to the concept of decision-making. Nondecision-making differs from decision-making in that direct and even tacit confrontation is avoided. Prior to the introduction of nondecision-making, power often was conceptualized as a conflict relationship—that is, a “power over” relationship. Traditional conceptualization of power, as suggested by Dahl, among others, posits that A gets B to do what B would not otherwise have done. Nondecision-making focuses not on such direct use of power, but on its indirect manifestations. As such, power can be exercised in the absence of a direct and overt threat. For example, assume that A gets B to engage in action X. As a consequence of B’s engagement in action X, it becomes unlikely that C will get B to engage in action Y; this is an indirect conflict relationship because A and C are not engaged in direct competition. What this suggests is that power relations can be both direct and indirect, and that they can involve the use of threats or not.

A primary function of nondecision-making is to maintain a mobilization of bias. Mobilization of bias represents a dominant set of beliefs, values, and institutional processes and procedures that work to privilege some groups in relation to others. This is in direct contrast to the pluralist view, which suggests that the marketplace of policy ideas is relatively open and accessible to various groups. Pluralists further argue that due to competition, the various groups possess the opportunity to influence the policy agenda, provided there has been sufficient political mobilization. Thus, groups hoping to influence policy decisions will not necessarily succeed in all of their attempts to influence policy, but neither will they be systematically denied access to influence the decision-making process. On the contrary, the theory of nondecision-making suggests that through a mobilization of bias, some groups are systematically denied access to the decision-making process. There are multiple forms by which the privileging of some can be achieved through nondecision-making; the threat of sanctions is one such form. Norms, rules, routines and procedures, values, and myths are often employed in the threat of sanctions. Nondecision-making can also employ the use of force. Another form of nondecision-making involves the use of the “rule of anticipated reactions”: Anticipated reactions result from situations where B, who has relatively less power than A, decides not to make a demand upon A in an effort to avoid confrontation, or out of the fear that such behavior would result in A’s invoking sanctions against him or her.

The result of nondecision-making is that certain persons, perspectives, issues, or conflicts are excluded or suppressed. Consequently, the scope of the debate is limited and contained to include issues perceived as “safe.” However, it is possible to challenge the mobilization of bias: To do so involves expanding the scope of participation of the decision-making process, and this requires enhancing the knowledge of participants. Community development corporations and progressive coalitions, among other groups, can all play a key role in expanding the scope of the democratic process.

NON-EXPECTED UTILITY THEORY

The expected utility/subjective probability model of risk preferences and beliefs has long been the preeminent model of individual choice under conditions of uncertainty. It exhibits a tremendous flexibility in representing aspects of attitudes toward risk, has a well-developed analytical structure, and has been applied to the analysis of gambling, games of strategy, incomplete information, insurance, portfolio and investment decisions, capital markets, and many other areas. This model posits a cardinal utility function over outcomes (usually alternative wealth levels) and assumes that an individual evaluates risky prospects on the basis of the expected value of his or her utility function. In situations of objective uncertainty (e.g., roulette wheels), this expectation is based on the objective probabilities involved. In situations of subjective uncertainty (e.g., horse races) likelihood beliefs are represented by the individual’s personal or subjective probabilities of the various alternative occurrences. First proposed by the Dutch mathematician Daniel Bernoulli in 1738 as a solution to the well-known Saint Petersburg paradox, the expected utility model has since been axiomatized under conditions of both objective and subjective uncertainty. Many consider these axioms and the resulting model to be the essence of rational risk preferences and beliefs.

In spite of its flexibility, the expected utility/subjective probability model has refutable implications, and beginning in the 1950s, psychologists and economists have uncovered a growing body of experimental evidence that individuals do not necessarily conform to many of the key axioms or predictions of the model. One well-known example, first demonstrated by the French economist Maurice Allais in 1953, consists of asking subjects to express their preferred option from each of two pairs of objective gambles. The majority of subjects express preferences that are inconsistent with expected utility, and they directly violate its primary empirical axiom, the so-called independence axiom. Although initially dismissed as an isolated example, the Allais paradox has been replicated by numerous researchers and found to be a special case of at least two forms of systematic violations of the independence axiom. Such departures have also been replicated using real-money gambles.

Starting in the early 1960s, researchers have also uncovered a class of systematic violations of the subjective probability hypothesis. The most well-known example, offered by Daniel Ellsberg in 1961, consists of an urn with ninety balls, thirty of which are red, with the remaining sixty being black or yellow in an unknown proportion. Subjects are asked to select from each of two pairs of bets on this urn, and they typically select in a manner inconsistent with well-defined likelihood beliefs in regard to obtaining a black versus a yellow ball. This finding was also originally dismissed, but the phenomenon has since been replicated by many researchers in a number of different examples. Choices in such experiments reveal a general preference for betting on objective rather than subjective events, a phenomenon that has been termed “ambiguity aversion.”

In response to these empirical violations, researchers have developed, axiomatized, and analyzed a number of alternative models of risk preferences and beliefs, most of which replace the expected utility formula with alternative formulas that individuals are assumed to maximize. The earliest of these models, proposed by Ward Edwards in the 1950s and adopted by Daniel Kahneman and Amos Tversky in the 1970s as part of their well-known “prospect theory,” was found to generate implausible predictions (namely that individuals would select some gambles with lower payoffs than other gambles). Economists have since developed and axiomatized non-expected utility models of risk preferences that avoid these difficulties, are consistent with the broad class of Allais-type violations of the independence axiom, and are capable of formal analysis and application to economic and other decisions. The most notable of these is the “rank-dependent expected utility model” of the Australian economist John Quiggin.

Researchers have also developed models of preferences over subjective prospects that are consistent with both Allais-type departures from expected utility risk preferences and Ellsberg-type departures from probabilistic beliefs. One such model, long informally discussed in the literature, axiomatized by Itzhak Gilboa and David Schmeidler, and known as “maximin expected utility,” posits a utility function and a set of subjective probability distributions over events. It assumes that individuals evaluate each bet on the basis of its minimum expected utility over this class of distributions. Another important model, again axiomatized by Gilboa and Schmeidler and known as “Choquet expected utility,” posits a utility function but replaces the classical (i.e., additive) probability measure of subjective expected utility with a nonadditive measure over events. It also replaces the standard expected utility formula with an alternative notion of expectation in respect to this nonadditive measure. Both models have been successfully applied to economic decision-making.

Nongovernmental Organizations (NGOs)

The term *nongovernmental organization*, or NGO, refers to a vast range of nonprofit organizations that are not a part of any government. They vary in size from a few people operating on a shoestring budget to huge globe-spanning organizations. Highlighted below are some crucial questions and controversies that are salient in shaping the political economy of NGOs as social actors, particularly in relation to their often assumed status as expressions of civil society; their relationship to social movements; and the ways they both constrain and enable progressive social change.

The number and visibility of NGOs have expanded dramatically since the 1970s, in part because neoliberal policies have reduced the role of the state in many areas. NGOs commonly work in numerous fields, including humanitarian and other social services; research, monitoring, and information provision; and advocacy around particular issues, such as the environment, health, the empowerment of marginalized communities, human rights, and the status of women and minorities. Many NGOs contract with states and intergovernmental organizations to provide services. During the early decades of NGO growth, they were celebrated as efficient providers of services and deliverers of empowerment. As a result, they became consultants to governmental and international agencies, particularly as representatives of the “grass roots.”

NGOs are sometimes called *voluntary organizations*, highlighting a presumption that social values, rather than profit or political power, are the primary motivators in the functioning of such organizations. These notions of values and voluntarism have led observers to see NGOs as expressions of civil society, similar to social movements, and to interpret their increased visibility as a strengthening of the influence of civil society in the affairs of the state and the economy.

Since the mid-1990s, the popular perception that NGOs are potential agents for diffusing development and enabling empowerment has increasingly been subjected to critical scrutiny in academia and in the community spaces where NGOs operate. Critics have pointed out that it is incorrect to assume that NGOs are automatically accountable to the “target groups” in whose name they work. Indeed, some pseudo-grassroots, or “astroturf,” NGOs have been set up by business or political interests to provide a misleading impression of grassroots action to advance their own agendas. Often astroturf groups try to hide their status as a vested interest.

More generally, the NGO form itself can blunt its potential for social activism for several reasons. First, NGOs commonly have an organizational hierarchy with paid staff and offices, so they must raise funds, either from donors or through contracting to provide services. This financial dependency frequently renders NGOs accountable to their funders. It also promotes a tendency toward professionalization. These factors often create tensions with movement-based models of social change that rely on mass mobilization.

Second, when NGOs rely on donors for funding, it becomes difficult for them to support alternative visions and local initiatives. For instance, David Hulme and Michael Edwards, in *NGOs, States and Donors* (1997), ask whether the interests, values, methods, and priorities of NGOs have become so tied with those of northern-government donors and “developing country-states” that they have now been “socialized” into the development industry. Have NGOs gained so much leverage, Hulme and Edwards wonder, because “they now have the social grace not to persist with awkward questions and the organizational capacity to divert the poor and disadvantaged from more radical ideas about how to overcome poverty?” (p. 3).

Third, NGO structures and project funding often lead to increased standardization and constrain the spaces for NGOs to learn in response to local concerns, leading to major gaps between advocacy and practice. As states increasingly outsource their functions to them, NGOs find themselves in a race “to do” rather than to “reflect.” As David Lewis and Tina Wallace put it in *New Roles and Relevance* (2000), “Finding ways of becoming learning organizations—as well as finding ways to increase accountability at all levels—largely continue to evade NGOs, yet the successful search lies at the heart of NGOs’ ability to respond in ways that are truly relevant” (p. xiv).

These processes, through which organizations working at the grassroots level lose their connection with their prime constituency and support base, have been called “NGOization.” There is thus an implicit or explicit critique that NGOs and their ties with the state are signifi-
Nonlinear Regression

A brief discussion of linear regression is essential in understanding nonlinear regression. One of the assumptions of the classical linear regression model is linearity of the functional form. A linear regression model can be written as:

\[ Y = \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k + \varepsilon, \]

where \( Y \) is the dependent variable, \( X_1, X_2, \ldots, X_k \) are the explanatory variables, and \( \varepsilon \) is the error term. A popular statistical technique to estimate the value of the parameters of this model is the classical linear regression where the optimization algorithm applies the least squares errors method to find the best fit. Given the classical assumptions, according to the Gauss-Markov theorem, the least squares coefficients are the best linear unbiased estimator (BLUE) of the population of regression coefficients.

Some regression models are intrinsically nonlinear in their parameters; therefore, application of linear regression estimates generates biased results. Nonlinear regression is an extension of the linear least squares regression for a much larger and general class of functions where the relationship between dependent and independent variable is not linear. As a result, the first-order conditions for least squares estimation of the parameters are nonlinear functions of the parameters. A general form of nonlinear regression equation is:

\[ Y_i = f(x_i, \theta) + \varepsilon_i, \]

NGOs WITHOUT “-IZATION”?

In a context in which NGOs have increasingly been called upon to help manage the problems produced by neoliberal policies and to pacify those who have been hardest hit by such policies, many small movements have found it impossible to exist without engaging with donor agencies or local and national NGOs in one form or another. The challenge before such organizations is to find creative ways to support their political work while also maintaining their accountability and transparency before the people they work for and work with. Despite the countless challenges, resistance to NGOization continues in many small organizations.

Nonlinear Regression

A brief discussion of linear regression is essential in understanding nonlinear regression. One of the assumptions of the classical linear regression model is linearity of the functional form. A linear regression model can be written as:

\[ Y = \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k + \varepsilon, \]

where \( Y \) is the dependent variable, \( X_1, X_2, \ldots, X_k \) are the explanatory variables, and \( \varepsilon \) is the error term. A popular statistical technique to estimate the value of the parameters of this model is the classical linear regression where the optimization algorithm applies the least squares errors method to find the best fit. Given the classical assumptions, according to the Gauss-Markov theorem, the least squares coefficients are the best linear unbiased estimator (BLUE) of the population of regression coefficients.

Some regression models are intrinsically nonlinear in their parameters; therefore, application of linear regression estimates generates biased results. Nonlinear regression is an extension of the linear least squares regression for a much larger and general class of functions where the relationship between dependent and independent variable is not linear. As a result, the first-order conditions for least squares estimation of the parameters are nonlinear functions of the parameters. A general form of nonlinear regression equation is:

\[ Y_i = f(x_i, \theta) + \varepsilon_i, \]
where $\mathbf{x}_i$ is a $(N \times 1)$ vector of independent variables, $\theta$ is a $(K \times 1)$ parameter vector, and $\varepsilon_i$ is an additive error term. A common example of intrinsically nonlinear functions is the Cobb-Douglas production function:

$$Q_i = \alpha L_i^{\beta_1}K_i^{\beta_2}\varepsilon_i,$$

where $Q_i$ is the output of firm $i$, $L_i$ is the labor input, $K_i$ is the capital input, and $\varepsilon_i$ is a multiplicative error term. Parameters of $\beta_1$ and $\beta_2$ are the elasticities of output with respect to labor and capital. Another example is the consumption function:

$$C_i = \alpha_i + \beta_1 Y_i + \beta_2 L_i + \varepsilon_i,$$

which reflects the uncertainty with respect to the way income affects consumption expenditures. In these examples, the terms in the models cannot be rearranged to apply the linear least squares.

Pioneers such as Jennrich (1969) and Malinvaud (1970) have advanced the econometric theory for nonlinear statistical models, while development of computing technology in the last few decades has allowed application of nonlinear models to statistical analysis of complicated relationships between variables. When the nonlinear functions cannot be transformed into linear form, econometrists use two common methods, the nonlinear least squares or the maximum likelihood, to estimate the parameters of the model. These approaches essentially search for a solution to the nonlinear optimization problem by minimizing the sum of squared errors or maximizing the likelihood function. Although there are very few limitations on the functional form of nonlinear regression, the parameters of the model are conceptually estimated in the same way as the linear least squares.

However, reaching a solution to a nonlinear optimization problem is a difficult task. A number of computational methods are available. The Gauss-Newton algorithm, a special case of the more general Newton-Raphson algorithm, is a popular method that linearizes the regression model by approximating $F(\theta)$ from a Taylor series expansion around an initial $\theta$ to minimize the residual sum of squares function. In the iterative linearization process, the nonlinear least squares method typically begins with guessed starting values for the parameters and computes the corresponding sum of squared residuals to reach a global minimum. Although the Gauss-Newton algorithm is more efficient in reaching a global minimum, it is less likely than the Newton-Raphson algorithm to locate the global minimum instead of a local one. Of course, since nonlinearity of the functional form violates the classical assumptions, the Gauss-Markov theorem does not apply to the nonlinear regression.

Econometrists typically ignore the possibility that the new error term created in the process of linearization may not meet the classical linear regression model assumption. Also, the nonlinear least squares method can become computationally expensive when the number of parameters to be estimated exceeds two. Since desirable properties of classical linear regression do not necessarily remain in the nonlinear least square estimator, the maximum likelihood estimator is often preferred. In fact, the two techniques are computationally similar.

In selecting functional form, several factors must be considered, including theoretical consistency, applicability, flexibility, computational difficulty, and factual conformity (Lau, 1986). While the underlying theoretical relationship between variables is important, various statistical techniques are used to allow the data to determine the appropriate functional form. In spite of its problem with the log of zero and negative values, the most popular technique for testing nonlinearity is the Box-Cox transformation method, which tests restrictions on a more general functional form. Some nonlinear equations, however, can be transformed into classical linear form, which would facilitate the estimation of their parameters through the classical least squares procedure. For example, taking the natural log of the Cobb-Douglas production function results in the following function, which is linear in parameters:

$$\ln Q_i = \alpha + \ln \beta_1 L_i + \ln \beta_2 K_i + \varepsilon_i.$$

In this case, the least squares estimates of the transformed variables would have the traditional desirable properties.

Nonlinear regression models are sometimes more consistent with the true relationship between variables and have found many applications in models such as the random parameter, continuous regime switching, and time-varying random parameter. Also, in spite of an overidentification tendency in the nonlinear models, the General Method of Moments (GMM) provides a mechanism to arrive at consistent parameter estimates without the normality assumption requirement. However, the use of nonlinear regression models has a few disadvantages. First, estimation procedures for nonlinear models are more complicated because of minimization of sum of square errors, especially when the number of parameters is large, because of minimization of sum of square errors and difficulty of finding the starting values for the iterative linearization process. Second, some measures of goodness of fit, such as the t-statistic and the F-statistic, are not directly compatible and cannot be used or require modification. Compatibility of other measures of goodness of fit such as the $R^2$ is debatable. Third, there is more ambiguity in the interpretation of the coefficients in nonlinear models because the derivatives of the regression are usually a function of $\theta$ rather than being constant. Overall, although the parsimony rule suggests that computationally more demanding estimators do not have better statistical properties, nonlinear maximum likelihood estimators tend to have better finite sample properties than simple alternatives.
Nonlinear Systems

All real world systems are nonlinear: Straight lines cannot, in practice, go on forever, nor can forces and interactions in natural or social systems. Nonlinearity arises in real economic systems both from human behavior—for example, wage demands varying as a function of the rate of employment—and from the interaction of economic variables—for example, the multiplication of wage rates by the number of workers to calculate the wage bill. Any model that omits these nonlinearities, either by assuming linear behavioral functions or by assuming that a variable remains constant in order to avoid interactive nonlinearities, necessarily reduces its capacity to model the actual economy.

Idealized linear systems can be hypothesized, and the mathematical analysis of these is long established, well-known, and generally results in closed-form symbolic solutions in which the system state at any point in time is a function of the system’s parameters. Moreover, in the vicinity of an equilibrium, the linear component of a system, which can be extracted from a mathematical model by a polynomial expansion, dominates the nonlinear components. Thus if a system is stable about an equilibrium, or can be constrained to remain in the vicinity of an equilibrium, its dynamics can be modeled using linear methods.

The mathematical analysis of nonlinear systems, on the other hand, is a recent development, and in general does not result in symbolic solutions. Instead, a nonlinear system must be numerically simulated, and in the subsets classed as either chaotic or structurally unstable, the time path of a system depends upon its initial conditions. Scientists in general therefore had a strong incentive to remain in the linear realm.

Since many real world systems did not meet the conditions for linear analysis, nonlinear analytic techniques were gradually developed, leading to what was initially called chaos theory and is now known as complexity theory. Nonlinear methods play a major role in most sciences today, but their uptake in economics has been noticeably more limited.

NONLINEAR ECONOMICS

Nonlinear economics began in the 1940s, when Hungarian economist Nicholas Kaldor (1908–1986) made the prescient observation that a model with linear ex-ante investment and savings functions could not explain the trade cycle. With savings and investment modeled as linear functions of employment, if the savings function were the steeper of the two, the model displayed “more stability than the real world appears, in fact, to possess.” On the other hand, if the investment function were steeper, then the system “would always be rushing either towards a state of hyper-inflation with full employment, or towards a state of complete collapse with zero employment, with no resting-place in between” (Kaldor 1940, p. 80). Since neither result could be justified, Kaldor surmised that “we are left with the conclusion that the $I(x)$ and $S(x)$ functions cannot both be linear, at any rate over the entire range” (Kaldor 1940, p. 81).

The adoption of nonlinear methods in economics after this insight was very limited, and Kaldor later argued that this was because economics took for granted “that the economy always approaches, or is near to, a state of equilibrium” (Kaldor 1972, p. 1239). Economists therefore tended to rely upon comparative statics methods, even when the relevant linear model was unstable under reasonable parameter values—as in the case of the linear model of supply and demand, which is unstable under the realistic condition that the price elasticity of supply exceeds that of demand.

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 523
Nonparametric Estimation

While Kaldor pointed out the need for nonlinear analysis in economics, the main pioneer of nonlinear models in economics was Richard Goodwin (1913–1996). Drawing his inspiration from the French mathematicians Henri Poincaré and Philippe Le Corbeiller (b. 1911), Goodwin developed many nonlinear models, with his signature contribution implementing Karl Marx’s class-struggle cycle model as a predator-prey system—in which technically, the capitalists were the prey and workers the predators.

There is now a substantial research tradition in nonlinear dynamics within economics that overlaps with the application of chaos, complexity, and evolutionary theories, and fractal analysis to economics. There are numerous nonlinear dynamical models of macroeconomics, microeconomics, and finance market phenomena, including the aggregate business cycle, the individual market cobweb cycle, and stock market crashes. Many econometric methods to test economic time series for nonlinear data structures (e.g., the Hurst exponent, the Brock–Dechert–Scheinkman (BDS) statistic, Smooth Transition Auto-Regression) exist, though their robustness at determining whether nonlinear causal structures exist in noisy linear time series is limited.

There are journals devoted to nonlinear economic analysis—such as Studies in Nonlinear Dynamics & Econometrics, and Nonlinear Dynamics, Psychology, and Life Sciences—as well as others where nonlinear analysis features frequently—such as the Journal of Economic Dynamics and Control, Macroeconomic Dynamics, the Review of Economic Dynamics, and Structural Change and Economic Dynamics. Most contributions from the developing field of econophysics could be characterized as essentially nonlinear, including those applying nonextensive statistical mechanics to the analysis of financial market data.

Despite this flowering, nonlinear analysis in economics is hampered by two dilemmas. The first, peculiar to economics, is that the dominant pedagogic and research tendency in economics is to model economic processes as equilibrium phenomena. The second, generic problem is best captured by John von Neumann’s (1903–1957) apocryphal aphorism that a general theory of nonlinear phenomena is akin to “a theory of non-elephants”: While linear analysis is well defined, the variety of nonlinear phenomena is so enormous that it bedevils systematic analysis (Bak and Paczuski 1995, p. 6690).

NONPARAMETRIC ESTIMATION

Nonparametric estimation is a methodology for estimating density functions or conditional moments of distributions without making any prior assumptions about functional forms. The data are allowed to speak for themselves in determining the shape of the unknown functions (Silverman 1986).

NONPARAMETRIC DENSITY ESTIMATION

In parametric estimation, if the underlying distribution is known to be normal, the data are used to calculate the mean μ and variance σ² of the distribution, substituting them into the formula for the normal density. Suppose
X is a continuous random variable, \( f(x) \) is the probability density function, and \( F(x) \) is the cumulative density function when \( X = x \). With \( h \) as the width of a bin or interval, the nonparametric naive estimate of \( f(x) \) is

\[
\hat{f}(x) = \frac{1}{nh} \sum_{i=1}^{n} I\left(\frac{X - x}{h}\right)
\]

where,

\[
I(\cdot) = 1 \text{ if } -\frac{1}{2} \leq \frac{X - x}{h} \leq \frac{1}{2} \\
= 0 \text{ if otherwise}
\]

Alternately,

\[
\hat{f}(x) = \frac{1}{nh} \sum_{i=1}^{n} K\left(\frac{X - x}{h}\right)
\]

The graph of the estimated density function (Figure 1) from equation (1) is not a smooth curve. Thus the weight function \( I(\cdot) \) is replaced by a kernel density function \( K(\cdot) \) that satisfies the condition \( \int_{-\infty}^{\infty} K(x) dx = 1 \). The revised nonparametric estimate of the density function is expressed in equation (2). Alternative choices on the kernel density function are provided in equations (4) through (6). The graph of a density function using kernel density weights is smooth and differentiable as illustrated by Figure 2.

**NONPARAMETRIC REGRESSION**

A regression function is an equation that explains and predicts movements in one variable (the *dependent* variable) as a function of movements in another variable or a set of other variables (the *independent* or *explanatory* variables). Having observed the independent variable \( X_i \), the regression function provides an average or expected value of the dependent variable \( Y_i \). For a set of \( n \) data points \( \{(X_i, Y_i)\}_{i=1}^{n} \), the regression function can be modeled as

\[
Y_i = E(Y_i | X) + e_i = m(X) + e_i, \quad i = 1, \ldots, n \quad (3)
\]

In equation (3), \( m \) is the unknown regression equation and \( e \) represents unknown stochastic disturbances. The aim of regression analysis is to estimate the regression function \( m \). The parametric approach assumes that the regression function has some prespecified functional form (such as logarithmic, inverse, quadratic, or cubic).
Nonparametric econometrics estimates the regression function $m$ without assuming any specific form.

An example of the two different approaches is illustrated by Figure 3. The straight, negatively sloped, dotted line represents a linear parametric function, while the other curve is a nonparametric estimate. Both curves model the rank of a harness racing horse (1 being high and 20 being low) as a function of its average speed at a racing track. The linear model is unable to represent a U-shaped regression relationship between the rank and speed of racing horses for certain ranges of horse speed.

The assumption that the estimate of the regression function is linear, that is, $m(X_i) = \beta_0 + \beta_1 X_i$, implies certain assumptions about the underlying data-generating process (Pagan and Ullah 1999). For example, if $\{X_i, Y_i\}_{i=1}^n$ is a bivariate normal density, then it can be shown that the mean of the conditional density of $Y_i$ given $X_i$ is $E(Y_i | X_i) = \alpha + \beta X_i$, where $\alpha = EY_i - \beta EX_i$ and $\beta = (\text{Var}(X_i))^{-1} \text{Cov}(X_i, Y_i)$. Thus, the linear specification for the regression function is valid only if the underlying data-generating process is normal. If the true distribution is not normal, then the true functional form of $m(X_i)$ is not linear, and least square estimates of the same, assuming a linear functional form, may be biased and inconsistent.

The question of which approach should be taken in data analysis was a key issue in a bitter feud between the statisticians Karl Pearson (1857–1936) and Ronald Aylmer Fisher (1890–1962) in the 1920s (summarized by Tapia and Thompson 1978). Fisher pointed out that the nonparametric approach gave generally poor efficiency that increased with the number of explanatory variables, thus giving rise to the well-known curse of dimensionality and requiring large data samples for accuracy. Moreover, the size of the required sample increases rapidly with the number of explanatory variables. At the same time, Pearson pointed out that the price paid for pure parametric fitting is the possibility of gross misspecification resulting in high model bias. The parametric and nonparametric estimation techniques support two different and yet very interesting viewpoints. The semiparametric estimation technique combines the two. Here, the relationship governing $Y_i$ is expressed as a linear function of some explanatory variables and a nonlinear function of remaining explanatory variables where the nonlinearity is unknown. The coefficients of interest are the slope coefficients of the linear part. P. M. Robinson (1988) shows that it is possible to construct estimators of the linear part that exhibit $\sqrt{n}$ consistency.

The basic principle behind the nonparametric estimation technique is to fit a window $h$ around every observation of the dataset and estimate the relationship or moment of interest in each window. A kernel density function $K(.)$ is used to give high weights to data points close to the window and low weights to data points far from the window. Thus the regression relationship is estimated, piece by piece or window by window, as shown in Figure 4. One of the advantages of nonparametric estimation is that it estimates the regression coefficients at every data point. For example, if the researcher is interested in estimating the relationship between a firm’s size and its export intensity, the nonparametric estimation technique will provide an estimate of the slope coefficient for every firm at every time period, thus giving a broader picture for analysis. Both parametric and nonparametric techniques share a common foundation. Parametric estimates are obtained by minimizing the sum of squares of residuals (SSR). Nonparametric estimates are obtained by minimizing the SSR weighted...
by the kernel density function at every data point. That is the reason why parametric estimates are a product of global fitting, while nonparametric estimates are obtained by local fitting. The conditional mean at point \( x \) is a weighted average \( \sum_{i=1}^{n} w(X_i; x) Y_i \) of \( n \) data points, where
\[
w = \sum_{i=1}^{n} K\left( X_i - x / h \right) / \sum_{i=1}^{n} K\left( X_i - x / h \right).
\]
The weights \( w(X_i; x) \) depend upon the kernel density function, the window width, \( X_i \), and the point \( x \) at which the conditional expectation is evaluated.

CHOICE OF KERNELS AND WINDOW WIDTHS

Some examples of kernels commonly used in the literature (Silverman 1986) are:

\[
\begin{align*}
\text{Epanechnikov:} & \quad K(t) = \frac{3}{4} \left( 1 - \frac{1}{3} t^2 \right) \sqrt{3} \text{ for } |t| < \sqrt{3} \\
& \quad = 0 \text{ otherwise} \tag{4}
\end{align*}
\]
\[
\begin{align*}
\text{Gaussian:} & \quad K(t) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}t^2\right) \tag{5}
\end{align*}
\]
\[
\begin{align*}
\text{Rectangular:} & \quad K(t) = \frac{1}{2} \text{ for } |t| < 1 \\
& \quad = 0 \text{ otherwise} \tag{6}
\end{align*}
\]

It is well known in the literature that the choice of kernels does not influence significantly the efficiency of estimates. The choice of window width is, however, crucial. Small values of \( h \) cause oversmoothing and high values lead to undersmoothing of the estimates. The optimum \( h \) is the one that minimizes the integrated mean squared error of \( m(x) = \int_{-\infty}^{+\infty} \left( \hat{m}(x) - m(x) \right)^2 dx \).

SCOPE OF NONPARAMETRIC ESTIMATION

The scope of applications for the nonparametric estimation technique is endless (Härdle 1990). It is particularly useful in time series applications, in treatment of extreme observations known as outliers, and in smoothing the gap of missing data by interpolating between adjacent data points. In general, nonparametric econometrics provides a versatile method of exploiting a general relationship between two or more variables without reference to a fixed parametric model.

BIBLIOGRAPHY

Nonparametric Regression

A regression model may be written generally as
\[
y_i = m(x_i | \theta) + \epsilon_i \tag{1}
\]
where the subscript \( i = 1, \ldots, n \) indexes observations, \( \epsilon_i \) is a random error term, uncorrelated with the regressor \( x_i \) and with zero expectation, and \( \theta \) represents a vector of parameters. Given \( E(\epsilon_i) = 0, E(y_i | x_i) = m(x_i | \theta) \); consequently, the function \( m(x_i | \theta) \) is often called the conditional mean function.

In ordinary least squares regression, the parameter vector is assumed to be of length \( K < \infty \) and the conditional mean function is assumed to be linear in parameters, e.g.,
\[
m(x_i | \theta) = \theta_1 + x_{i2} \theta_2 + \ldots + x_{iK} \theta_K.
\]
Moreover, in small samples the errors are typically assumed to be normally distributed in order to facilitate inference. With maximum likelihood estimation, the parameter vector is again assumed to be of finite length \( K \), and a particular form is assumed for the conditional mean function, although linearity in parameters is not necessary. In addition, the errors are assumed to come from a particular family of distributions (e.g., normal, beta, gamma, etc.); with independent sampling, the likelihood function can then be derived as a product of marginal probability density functions, each evaluated at one of \( n \) sample observations.

Nonparametric regression involves using one of several techniques to avoid the need to assume specific functional forms for the conditional mean function as well as the distribution of the error terms in (1). By making fewer assumptions, one avoids the risk of mis-specifying either the conditional mean function or the distribution of the errors, which can lead to biased and inconsistent estimation. Moreover, with nonparametric regression techniques, the underlying, true model that is estimated can itself be viewed as nonparametric, in the sense that it can-
not be represented by a function involving a finite number of parameters. In other words, the parameter vector \( \theta \) can be assumed to have an infinite number of elements. Consequently, the variety of shapes of conditional mean functions that can be estimated by nonparametric regression methods is far greater than what is possible with more conventional parametric estimation methods such as ordinary least squares or maximum likelihood. However, the increased flexibility comes with some costs; in particular, inference is often more difficult, computational burdens are greater, and rates of convergence are slower with nonparametric methods than with parametric methods.

Several nonparametric regression estimators have been developed. One of the most widely used is the Nadarya-Watson estimator (Nadarya, 1964; Watson, 1964) given by

\[
\hat{\mu}_h(x) = \frac{1}{n} \sum_{i=1}^{n} K_h(x - X_i) Y_i, \quad \text{where } K_h(\cdot) = K(\cdot/h) \quad \text{is a weighting, or kernel, function that is symmetric and integrates to 1; i.e., } K(-t) = K(t) \quad \text{and } \int K(t) dt = 1. \quad \text{A wide variety of functions satisfy these conditions; for example, any symmetric probability density function can be used as a kernel function, as well as any even-order polynomial over some interval from } -\zeta \text{ to } +\zeta \text{ with coefficients chosen so that the polynomial integrates to 1 over this interval.}
\]

Although researchers using the Nadarya-Watson estimator (as well as other nonparametric estimators) must choose both a kernel function and a value for the smoothing parameter, the choice of kernel function is less impor-
tant in determining estimation error than the choice of a value for the bandwidth. The bandwidth \( h \) determines the degree of smoothness of the estimator. As \( h \to 0 \), bias of the estimator diminishes but variance increases; as \( h \to \infty \), bias increases while variance decreases. A number of data-driven techniques have been developed to optimize the choice of \( h \) with respect to one of several criteria; for example, cross-validation methods can be used to choose a value for \( h \) that minimizes either mean integrated square error or asymptotic mean integrated square error; see Pagan and Ullah (1999) for details. Alternatively, less computationally burdensome plug-in procedures proposed by Sheather and Jones (1991) can be used to choose an optimal value for the bandwidth.

Figure 1 provides an example illustrating the Nadarya-Watson estimator. With the same data displayed in each panel of Figure 1, estimated regression lines are shown for the ordinary least squares (OLS) estimate of the model

\[
y_i = \beta_0 + \beta_1 x_i + \epsilon_i
\]

and Nadarya-Watson kernel estimates of (1) with the standard normal density function used as the kernel function and with three different values of \( h \): 0.1, 1.0, and 4.0. The data clearly follow a nonlinear pattern, which the OLS estimator of (3) cannot replicate. With \( h = 1 \), the kernel estimator captures the pattern of the data nicely, providing a reasonably smooth estimate of the regression curve.

When the bandwidth is reduced to 0.1, the kernel estimate becomes jagged, while increasing the bandwidth to 4.0 results in an estimated curve that is much flatter than the estimates obtained with smaller bandwidths. The two panels in the bottom row of Figure 1 illustrate the tradeoff between bias and variance associated with larger or smaller values of \( h \) as discussed above.

The Nadarya-Watson estimator, when evaluated at an arbitrary point \( x \), is simply a weighted average of values \( Y_i \) in a neighborhood of \( x \); the size of the neighborhood and the weights given to each \( Y_i \) are determined jointly by the kernel function \( K(\cdot) \) and the bandwidth \( h \). Local polynomial estimators, by contrast, estimate the conditional mean function by fitting locally a \( p \) th-order polynomial to the data. This approach offers several advantages over the earlier Nadarya-Watson estimator, as discussed by Fan and Gijbels (1996). Setting \( p = 1 \) yields a local linear estimator, which has less bias but no greater variance than the Nadarya-Watson estimator. In addition, while the Nadarya-Watson estimator is inconsistent near boundaries of support for \( x \), local polynomial estimators remain consistent near such boundaries. While estimation of regression derivatives is possible using modifications of the Nadarya-Watson estimator, estimation of derivatives is straightforward with local polynomial estimators. As with the Nadarya-Watson estimator, a number of techniques have been developed to optimize the choice of bandwidth when local polynomial estimators are used, as discussed by Fan and Gijbels (1996).

**NONVERBAL COMMUNICATION**

By virtue of a series of discoveries and conceptual departures in the social sciences, our understanding of the process of human communication has been expanded to include nonverbal communication. In the words of Ashley Montagu and Floyd Matson in *The Human Connection* (1979): "It is not merely a hidden dimension or a silent
Nonverbal Communication

language that has been uncovered by the new wave of scientific explorers; it is more like a neglected universe of discourse and intercourse. We are becoming aware that the verbal domain is only the tip of the iceberg of communicative experience—that there is more, much more, to human dialog than meets the ear” (p. xiii). This entry discusses key ideas from the vast research literature on nonverbal communication (NVC).

Nonverbal behavior (NVB) is usually divided into several categories. One category is paralanguage, which refers to the content-free vocalizations and pauses associated with speech. Research conducted by Starkey Duncan and Donald Fiske (1979) shows how paralinguistic behaviors serve as regulators of social interaction. Another category is facial expressions. Paul Ekman's research has shown how expressions indicate primary emotions (for example, see his 1992 article). A third category is kinesics or body language. The research reported by Ray Birdwhistell in Kinesics and Context (1970) is an example of the value of detailed recording of gestures and bodily movements. A fourth category is visual behavior, which includes gazing. Michael Argyle's research, reported in Bodily Communication (1975) and elsewhere, has elucidated the meaning of and social functions served by various patterns of eye contact between people. The study of spatial behavior or proxemics is another aspect of NVC research. Edward Hall's categories of interpersonal distance influenced the study of communication and culture (see The Hidden Dimension, 1966). Georg Simmel's writing about spatial relations throws light on how space can reflect a group's social standing as being dominant or marginal in a society (see Allen, 2000). The synergistic effects of these categories are illustrated by Albert Mehrabian's multiple-channel research summarized in his 1972 book Nonverbal Communication.

Each of the nonverbal channels is understood in terms of both interpretation—referred to as decoding—and communication, known as encoding. These functions are related: The interpretive function leads observers to infer the communicator's intentions; the communicative function is used to influence the observers' attribution of intentions. The knowledge generated by research provides a tool for agents of influence such as advertising executives and politicians. Certain NVBs have been shown to provide a window into emotions and intentions: For example, in her 2006 article, Christine Harris shows the NVBs and muscle activations that indicate the feeling of embarrassment (in succession—eyes down, smile control, head away, gaze shifts, face touch); and, in their 1982 book on Nonverbal Communication, Daniel Druckman, Richard Rozelle, and James Baxter show that deceivers displayed more frequent leg movements, less time looking at the interviewer, and more fidgeting with objects than honest and evasive role-players in their experiments. These are some of the cues that can be used to diagnose psychological states and lying (referred to as decoding); they are also the cues that can be used to disguise one's feelings or intentions (referred to as encoding).

It would seem then that the research findings provide useful information for managing impressions. However, the research also suggests that the process may be more difficult than it seems. In a 1985 chapter, Bella DePaulo and her colleagues review evidence on the impact of controlling NVBs in order to perpetrate a lie. Pointing to a phenomenon referred to as leakage, these findings show that when certain nonverbal channels, such as facial expressions, are orchestrated to hide an intention, other channels, subject to less conscious control, can be revealing. Words and facial expressions have been found to be easier to control than body movements and such paralinguistic behaviors as tone of voice. These researchers also show that highly motivated liars may be easier to catch than their less motivated counterparts: When the stakes for pulling off a lie are high, more-difficult-to-control nonverbal channels are more revealing than verbal clues; less motivated liars are more likely to give themselves away with words. Thus, both context and channel are important for diagnosis. Likewise, they are important for the communicator's attempts to create certain impressions.

Another issue is the extent to which the findings are universal. Culture has been shown to influence expressions: Based on a review of the research, Randall Gordon and his colleagues concluded that "the events that elicit emotions vary from culture to culture, but the particular facial muscle movements triggered when a given emotion is elicited may be relatively universal" (2006, p. 85). Cultural influences are referred to as display rules. These rules serve to control expressions that would be inappropriate in certain settings. Numerous studies have found differences among cultures in each of the NVB channels: Many of these studies focus on preferences for spacing or interaction distances; some show differences between cultures in gazing behavior, while others examine paralinguistic behaviors. (See, for example, Michael Argyle's 1986 article on display rules dealing with intimacy.) However, while the cross-cultural comparisons are informative, the studies provide limited insight into the situations that arouse such feelings as guilt, shame, or stress within cultures. Cultural interpretations of situations—for example, as social transgressions—are central to the idea of display rules and have implications for the way we diagnose leaked NVBs.

Professional cultures also influence expressions and their interpretation. For example, when considering the field of international politics, four questions can be asked: What is the state of the leader's health? To what extent do the statements made by national representatives reflect
actual policies? How committed are representatives to the positions put forward? How secure is the representative’s political status? Clues about what to look for are provided by NVC studies. A furrowed brow and raised eyelids together with change in vocal tone and heightened pitch suggest pain; deviations from baseline NVBs may indicate deception; an increase in the amount of NVBs expressed in several channels may signal strong commitment; and spatial behavior may provide clues to political status. These indicators direct attention to relationships between nonverbal channels, abrupt changes in expressions, and the intensity of nonverbal displays. They provide a structure for focusing attention on relevant details—that is, they suggest where to focus attention and what to look at. But they can also be misleading. Professional politicians are adept at masking intentions and feelings, particularly in the channels that are easier to control (facial expressions, spatial behavior). For this reason, knowledge about professional socialization and norms provides a broadened appreciation for the meaning of communication. (For more on NVC in the context of international politics, see the 2006 chapter by Gordon and his coauthors.)

**NONWHITES**

Social scientists often classify and study individuals and groups based upon shared characteristics. A racial group is comprised of individuals who share similar physical characteristics including skin color. The U.S. Census uses the following racial categories: American Indian or Alaska Native; Asian; Black or African American; Native Hawaiian or Other Pacific Islander; White and Some Other Race. There are also two minimum categories for ethnicity: Hispanic or Latino and Not Hispanic or Latino. Hispanics and Latinos may be of any race. The labels as well as the definition for the aforementioned racial groups have changed over time. For decades, individuals could only identify with one racial group. A historic change took place with Census 2000 that permitted individuals to identify with more than one race. This change to the enumeration questionnaire is indicative of how definitions about race can change over time and that these changes are often politically contested. Collectively, individuals identifying themselves as multiracial, Asian, black, Native American, or “other” are referred to by sociologists as “nonwhites.” This typology has its strengths and weaknesses, particularly for conducting research.

Research has shown that nonwhites have relatively less access to wealth, status, and power and thus fewer life chances, relative to whites that in American society are considered the dominant racial group. It is for that reason that sociologists as well as other social scientists, in conducting research, study these populations and changes over time jointly. Yet the categorical grouping together by social scientists of all minority groups often fails to recognize the diversity within and between racial groups.

For example, while blacks, Native Americans, Asians and “others” are relatively disadvantaged when compared with their white counterparts, all nonwhites are not
equally disadvantaged. On selected social and demographic indicators some Asian ethnic groups, for instance, fare better than individuals who the U.S. Census would consider white. Still other nonwhites such as blacks and Native Americans have been shown to be relatively disadvantaged when compared with their white counterparts. These findings have been observed consistently on selected social and demographic variables including on educational attainment, homeownership, housing values, income, and occupational prestige.

Various Asian ethnic groups, for example, are not equally advantaged relative to whites or Native Americans equally disadvantaged relative to whites. While Asians with Indian ancestry may have relatively high levels of education, Asians of Vietnamese descent may have relatively low levels of education. Similarly, blacks with recent ancestry in Africa or in the Caribbean may have higher incomes relative to native-born blacks. Consolidating individuals who do not possess physical characteristics that are similar to those of the dominant group also means that certain ethnic groups within the larger racial classifications are understudied due to their relatively small population size.

The term nonwhite can also be used to describe a group of people whose skin color is distinctive from the dominant racial group in America, despite the contention by scholars that there are no pure races. Social sciences tend to view racial categories not as purely biological rather as socially constructed. Nonwhites, therefore, share distinguishing physical characteristics that are the basis for the unequal treatment they may experience.

The term nonwhite highlights the relative disadvantages experienced by individuals with less power over their lives than the dominant group. At the same time, the term nonwhite ignores both subpopulations and within group differences on various social outcomes.

NONZERO-SUM GAME

In game theory, nonzero-sum games (more precisely known as nonconstant-sum games) include many examples in which the sum of the payoffs to the players varies according to the strategies chosen. These cases are often more relevant to issues in social science and public policy than are zero-sum (and more generally constant-sum) games. From a mathematical point of view, however, they raise problems of solution that do not arise when the sum of payoffs is a constant.

An example arises in the case of public goods. Suppose that two agents acting independently can each earn payoffs of ten. However, each has the option of contributing three units from his wealth to produce two units of a “public” good that benefits both players equally. The strategies then are “contribute” or “do not contribute,” and the game can be summarized in tabular normal form as shown in Table 1.

The Table is read as follows: Agent 1, by choosing his strategy, chooses the row, and Agent 2 chooses the column. In the chosen cell, the first payoff is to Agent 1 and the second to Agent 2. For example, at the top left, both agents contribute, leaving seven units each of private wealth, but four units of the public good are produced, adding four additional units of benefits for each of the two agents.

A game of this sort admits two broad classes of solution: cooperative and noncooperative. Cooperative solutions allow for the possibility that the agents may form a coalition and enter into a binding agreement to choose a joint strategy. In this case, it seems likely that they would both choose to contribute, because this choice makes both better off, while each would refuse to contribute if the other does not. Noncooperative solutions assume instead that there are no trustworthy commitments to joint action. In the case of the public goods dilemma, each agent can reason that he is better off choosing not to contribute, whatever the other may do, and moreover that the other player can reason in the same way. As a consequence, it seems that each would choose not to contribute. Therefore, “do not contribute” is the equilibrium of the game. The fact

Lori Latrice Sykes
that each agent has an unconditional motive to choose the equilibrium makes this game an instance of a social dilemma. In addition to public goods, noncooperative equilibrium concepts are applied to competition in industry, international rivalries, population dynamics in evolutionary biology, and many other issues.

In cooperative solutions of larger and more complex games, questions may arise with respect to bargaining and the division of the benefits from the common strategy and the stability of coalitions and agreements, leading to a number of alternative concepts of solution. Among noncooperative solutions, the equilibrium concept is dominant, but ambiguities can arise with respect to information and learning, and some alternative solution concepts have been explored.

A half-century of experimental work in social psychology, political science, and economics has indicated that both cooperative and noncooperative solutions influence human behavior, but also that real human beings often reason less carefully than the hypothetical agents of game theory.

NORMAL PROBABILITY DENSITY FUNCTION
SEE Probability Distributions.

NORMAL SCIENCE
SEE Paradigm.

NORMALIZATION
The issue of normalization arises when the nature of an economic model is unaffected by a vector of structural parameters (coefficients) that can be arbitrarily scaled. This scaling is formally defined as normalization. A primary example is the simultaneous-equation framework of money supply and money demand:

\[ \alpha_y M_t + \alpha_y R_t = \epsilon_t^y \]  \hspace{1cm} (Money Supply)  \hspace{1cm} (1)

\[ \beta_y M_t + \beta_y R_t = \beta_y y_t + \beta_y P_t + \epsilon_t^D \]  \hspace{1cm} (Money Demand)  \hspace{1cm} (2)

In equations (1) and (2), \( M_t \) stands for money stock, \( R_t \) for the nominal interest rate, \( y_t \) for real output or real income, and \( P_t \) for the price level. All variables are expressed in log value. The money-supply and money-demand shocks, \( \epsilon_t^y \) and \( \epsilon_t^D \), are random variables with zero mean and are independent of each other in probability distribution.

It has been long recognized that the parameter \( \alpha_y \) and \( \beta_y \) in equations (1) and (2) can be normalized (scaled) in any way, with no consequence on economic interpretations of this equation. The conventional rule is to normalize the supply equation (1) as

\[ R_t = \alpha_y M_t + \epsilon_t^y \]  \hspace{1cm} (3)

with \( \alpha_y = \frac{\alpha_y M_t}{\alpha_y R_t} \) and \( \epsilon_t^y = \frac{\epsilon_t^y}{\alpha_y} \), and to normalize the demand equation (2) as

\[ M_t = \beta_y R_t + \beta_y y_t + \beta_y P_t + \epsilon_t^D \]  \hspace{1cm} (4)

with \( \beta_y = \frac{\beta_y M_t}{\alpha_y M_t} \), \( \beta_y = \frac{\beta_y M_t}{\alpha_y M_t} \), \( \beta_y = \frac{\beta_y M_t}{\alpha_y M_t} \), and \( \epsilon_t^D = \frac{\epsilon_t^D}{\beta_y} \).

The coefficient \( \alpha_y \) is often interpreted as an interest elasticity of the money supply, \( \beta_y \) as an elasticity of demand for money, \( \beta_y \) as a money-demand elasticity with respect to changes in output or income, and \( \beta_y \) as an elasticity of demand for money with respect to changes in the price level. The following analysis for this example applies to any supply-demand framework in which \( M_t \) is replaced by the quantity of a commodity under consideration, \( R_t \) replaced
by the price of this commodity, and $y_t$ and $P_t$ replaced by any variables that affect supply but not demand.

In the 1970s econometricians began to recognize that how the supply or demand equation is normalized affects the estimator of the supply or demand elasticity ($\alpha_M$ or $\beta_p$) when the two-stage least squares (2SLS) approach is employed. The quality of this estimator is sensitive to the strength of instruments used in the 2SLS estimation, which in turn depends on whether the price variable or the quantity variable is normalized to be on the left-hand side of the supply or demand equation, as in (3) or (4). There are other methods that one can use to estimate the supply and demand equations. One dominating alternative is the full-information maximum likelihood (ML) approach. This approach used to be computationally infeasible for many practical problems. As computing technology improves over time, the ML approach has become more feasible to implement. One advantage of the ML approach over the 2SLS approach is that the economic meaning of the ML estimates will not be affected by normalization.

Not until the 1990s, however, did it become known that normalization matters to small-sample statistical inference about the ML estimates. Likelihood-based small-sample inferences are affected because normalization governs the likelihood shape around the ML estimates. A poor normalization can lead to multimodal distributions, disjoint confidence intervals, and very misleading characterizations of the true statistical uncertainty.

Related to this discovery, in the Bayesian econometric literature there have been theoretical results showing that normalization can lead to ill-behaved posterior distributions when a flat or symmetric prior is used. The empirical and policy significance of these results has been largely unexplored until very recently. Daniel Waggoner and Tao Zha (2003) and James Hamilton, Waggoner, and Zha (2007) show that normalization can alter economic interpretations of dynamic responses of the variables $M_t$ and $R_t$ to a supply or demand shock $e^S_t$ or $e^D_t$ in the above example. They use this and other examples to demonstrate that inadequate normalization may confound statistical and economic interpretations.

There are a variety of economic applications in which normalization plays an important role in likelihood-based statistical inferences. Unfortunately, there is no mechanical way to implement the best normalization across different models. As a practical guide, therefore, it is essential to report the small-sample distributions of parameters of interest rather than the mean and standard deviation only. Bimodal and wide-spread distributions are the first clue that the chosen normalization may be inadequate. Carefully chosen normalization should follow the principle of preserving the likelihood shape around the ML estimate. A successful implementation of this principle for normalization is likely to maintain coherent economic interpretations when statistical uncertainty is summarized.

Normative Social Science

Early in the educational process, the novice social science student is typically introduced to two kinds of research: positive and normative. Positive social science is allegedly about what is—the unbiased, objective facts of the world, untainted by value judgments of an ethical, political, or aesthetic sort. By contrast, normative social science is about what ought to be. Apparently unlike positive science, normative social science admits to bias, subjectivity, the moral taint. Much confusion has arisen from the alleged positive/normative distinction, a distinction that is known in philosophy circles as the fact/value dichotomy.

Advanced students of social science, excluding some students of sociology and most students of anthropology, are not encouraged any more than are beginners to clarify the nature of the confusion. Most philosophers, but to repeat, only a few social scientists, reply that this is because the distinction between positive and normative, facts and values, what is and what ought to be, cannot be clarified; they are inextricably entangled.

The word normative descends from the Latin norma, meaning a carpenter’s T-square, a rule, or a prescription. In ordinary English, a norm is what is expected, what is customary, what is habitual. In mathematics, the norm is a standard unit. In economic discourse, ever since John Neville Keynes (1852–1949) published his influential On the Scope and Method of Political Economy (1891), normative conflates the Latin norma and the ordinary English norm, yielding something like, as Keynes put it, a “regulative science … a body of systematized knowledge discussing criteria of what ought to be.” Like his muse, David Hume (1711–1776), Keynes (father of the great
The distinguished economist and philosopher Amartya Sen provides an example of such an error. For much of his career Sen (the 1998 Nobel laureate in economics) has been preoccupied with four areas of research: social choice, preference theory, capabilities, and the economics of poverty and famine. For example, in *Inequality Reexamined* (1992), he brings attention to a contradiction in “positive” preference theory, an error with ethical and political ramifications. Sen observes that economists and an increasingly large number of sociologists and political scientists accept “individual choice” and “revealed preference” to be foundational concepts in their positive science. Therefore, they argue, statistical measurements of income and consumption, and even the data from social surveys, are capable of extracting the parameters of “desire” or, to use the utilitarian term, of “happiness” achieved at various levels. Utility functions themselves cannot be observed. But the choice set of a rational economic actor is, by the logic of choice, relative price, and revealed preference, de facto observable, and so (indirectly) is a person’s desire. But, Sen observes, impoverishment and deprivation can so reduce a person’s desire and self-worth that what they say and do about their own desire is far below—and different from—what they would actually do (let alone what they “should” do) were they in fact flourishing at normal levels. According to Sen:

The problem is particularly acute in the context of entrenched inequalities and deprivations. A thoroughly deprived person, leading a very reduced life, might not appear to be badly off in terms of the metric of desire and its fulfillment, if the hardship is accepted with non-grumbling resignation. In situations of long-standing deprivation, the victims do not go on grieving and lamenting all the time, and very often make great efforts to take pleasure in small mercies and to cut down personal desires to modest—“realistic”—proportions…. The extent of a person’s deprivation may not at all show up in the metric of desire-fulfillment, even though he or she may be quite unable to be adequately nourished, decently clothed, minimally educated, and properly sheltered. (Sen 1992, quoted in Putnam 2002, p. 59)

As the philosopher Hilary Putnam puts it, “‘Capabilities,’ in Sen’s sense, are not simply value functionings”; that is, they are not continuous utility functions derived from a preexisting and exogenously given preference ordering. They are “freedoms to enjoy valuable functionings”; that is, they are social and economic preconditions for performing a job well, keeping a clean house, casting a democratic vote, or reading a book by Adam Smith (Putnam 2002, p. 59). Social scientists disagree about what counts as a value functioning, and, importantly, on how one would go about measuring them in a capabilities approach. For example, will an annual income of $20,000 (in constant 2008 dollars) suffice, by Sen’s standards, for a family of four living in the United States? Or is income level alone a lame metric of deprivation? What, if anything, should society do to help expose and heal any wounds of deprivation? The point of the example is not to answer a policy question; it is to suggest that normative judgments reside deep in the heart of the neoclassical preference-theoretic approach.

Thomas Schelling, Albert O. Hirschman, and other economists have found it easy to identify other mischiefvous errors in economics caused by an unexamined faith in positive analysis. For example, in “Against Parsimony: Three Easy Ways of Complicating Some Categories of Economic Discourse” (1984), Hirschman, working in a vein similar to his Princeton colleague, the philosopher Harry Frankfurt, shows that metapreferences—preferences over preferences—are a proper object of economic analysis, more realistic, more humane, but also capable of some prediction.

Metapreferences are about the kind of self one would like to be in the future, not the self one is today, at current prices and budget constraints. Metapreferences require reflection, the ability to step back and evaluate the spiritual and material constitution and direction of one’s life. Bigots, for example, may find on reflection that they prefer human equality and the Golden Rule; party animals may decide on reflection that they are better off sober (or at least drinking less and at home with family and friends rather than in expensive nightclubs with strangers). If the metapreferences differ from the actual, Hirschman notes, then eventually, of course, one could expect to observe a preference change. How to observe a preference change is a matter of usual scientific debate and invention (Hirschman 1982 [2002]; Kuran 1995). But the main point here is that reflection about one’s future self is itself a value judgment, even if one does not change one’s preferences. So if an economist assumes in an economic model,
Norms

following the positive approach of Milton Friedman (1912–2006) and Gary S. Becker, that people have, for instance, a “taste for discrimination” (Becker [1957] 1971) or excessive partying or nationalism, then at minimum economists are obliged to state that they are examining the wanton, and not the reflective, side of human life. But that move, Hirschman and Sen would probably agree, reveals a normative judgment in positive economics. It makes transparent the assertion of human wantonness.

Normative and positive continue to figure prominently in social science discourse and education. But the distinction rests on the so-called fact/value dichotomy, long collapsed.

NORMS

Social scientists invoke the concept of norms to explain a broad range of human behaviors. No universally agreed-upon definition of norms exists, but many definitions share three components (Horne 2001, pp. 3–5). First, norms are rules that prescribe or proscribe a behavior or set of behaviors. Second, norms are enforced by external sanctions (rewards and punishments furnished by a source other than their target). These sanctions can be material (e.g., financial bonuses or fines) or symbolic (e.g., expressions of approval or disapproval). Third, norms are consensual, group-level phenomena. Group members recognize the existence of norms and feel entitled to enforce them. Some debate remains over whether norms, once established, are unconditional, clear, and generally followed (as in many rational choice theories), or conditional, unclear, and constantly negotiated (as in many symbolic interactionist theories) (Hechter and Opp 2001, pp. 394–396).

This definition distinguishes between norms and similar concepts, such as values and attitudes. Norms differ from values in that they are enforced by external sanctions, whereas values are enforced only by internal sanctions, such as feelings of pride or shame (Hechter and Horne 2003). Norms differ from attitudes in that norms are consensually held and legitimated by the group, whereas attitudes are a property of individuals. Norms also differ from latum in that a central authority (such as the state) formally creates and enforces laws, while people informally create and enforce norms. Some scholars distinguish between norms and conventions, the primary difference being that the direction of conventions is arbitrary (Coleman 1990). For example, it does not matter whether people drive on the left or the right side of the road, so long as everyone follows the convention of driving on the same side.

Norms shape social behavior by constraining action, and may be beneficial or harmful. Beneficial norms make society possible by protecting people from exploitation. Humans existed for thousands of years without the protections of a formal legal system (de Quervain et al. 2004), and the actual exercise of law remains limited due to resource constraints (Ellickson 1991). In the absence of law, norms regulate behavior and prevent people from routinely using force and fraud for private gain (Ellis 1971). Such norms include those that ensure that people look after their neighbors’ children or livestock, punish laziness at work, respect cease-fire and arms-control agreements, reciprocate favors, help strangers, and otherwise contribute to a stable society.

Harmful norms may constrain individual achievements. Such norms include leveling norms that prevent advancement by members of disadvantaged ethnic groups (Portes 1998, pp. 15–18), or norms mandating that women confine their activities to domestic pursuits and forego the labor market. Norms can also sustain harmful practices that a majority of the group opposes, including...
informing on one’s neighbors in repressive regimes and binge drinking on college campuses (Centola et al. 2005). Some norms also encourage dangerous practices such as dueling (e.g., Axelrod 1986, p. 1095).

Norms constrain the behavior of corporate actors as well as individuals. Firms sometimes adopt rules or structural changes that conform to norms in order to enhance their legitimacy, even when these practices run counter to market pressures (Meyer and Rowan 1977). Territories gain recognition as states in part by conforming to international norms defining the requirements for statehood. Failure to do so can result in loss of statehood and the attendant privileges (Meyer et al. 1997).

Given the widespread use of norms as an explanatory device, an important task for the social sciences is to explain the conditions under which norms emerge, change, and persist. Early functionalist explanations of social norms argued that norms arise because they benefit society, but this view has been discredited and generally abandoned. Because actors enforce norms through sanctioning, a number of theories seek to understand why actors sanction particular behaviors.

Structural features of situations can influence norm emergence. Conformity tends to increase as the size of the majority in favor of the norm increases (Asch 1951). Such factors as low levels of trust and a high risk of exploitation motivate the creation of norms that reduce the risk of exploitation (Yamagishi 1988). Network density may help coordinate sanctioning (Coleman 1990), and the threat of collective punishment can produce norms that mitigate that risk (Heckathorn 1988). In addition, actors with greater structural power possess greater ability to create, enforce, or undermine norms that serve their own interests at the expense of vulnerable actors (Coleman 1990).

People also follow and enforce norms in order to gain approval and signal that they are trustworthy interaction partners, thus encouraging others to profitably exchange with them (Homans [1951] 1992; Horne 2004). People increasingly enforce metanorms (by rewarding those who sanction deviants) as the direct and indirect benefits of exchanging with others increases (Horne 2004). Enforcing norms to gain approval can backfire, as when people enforce norms that the majority privately disdains because they falsely believe the norm to be popular (Centola et al. 2005).

Norms may also develop through a process of cultural evolution in which a norm, once established, provides greater average benefits to those who follow the norm than those who do not (Axelrod 1986; Bendor and Swistak 2001). Similarly, people may also learn to support norms via trial and error (Macy 1993).

Affective processes motivate norm enforcement. Emotional responses lead people to punish theft, walk away from profitable but unethical business deals, and help strangers in need, even when these actions contradict their short-term material interest (Frank 1988). Neurologically, people experience greater levels of activation in a reward center in the brain when they punish people who have behaved in an untrustworthy manner (de Quervain et al. 2004).

A number of important questions regarding norms remain. Broadly, it is important to continue to develop explanatory theories and empirical tests of norm emergence. Other pressing questions include how norms acquire content (Hechter and Opp 2001), how harmful norms emerge (e.g., Centola et al. 2005), and how norms and laws interrelate. Answers to these and related questions will deepen our knowledge of this fundamental but often opaque concept.

North, Douglass

1920–

The American economist Douglass Cecil North shared the 1993 Nobel Memorial Prize in Economic Sciences with Robert W. Fogel, “for having renewed research in economic history by applying economic theory and quantitative methods in order to explain economic and institutional change” (Nobel Foundation 1993). North's work spans decades of inquiry into American economic history, European economic history, and economic development. His most recent research explores the intersection of economics and cognitive science.

North was born on November 5, 1920, in Cambridge, Massachusetts. He graduated from the University of California, Berkeley in 1942 and, following a stint in the merchant marine, he received his PhD from Berkeley in 1952. He started his career at the University of Washington in 1950, where he remained until 1983, when he moved to Washington University in Saint Louis. The influence of his colleagues, such as Yoram Barzel and Stephen N. S. Cheung, is apparent in North's emphasis on property rights, transaction costs, and culture.

North has also held visiting positions at Cambridge University, Rice University, and Stanford University's Center for Advanced Studies in the Behavioral Sciences. He currently holds an appointment as the Bartlett Burnap Senior Fellow at Stanford University's Hoover Institution. A former president of the Economic History Association and the Western Economic Association, North has also served as a member of the board of directors of the National Bureau of Economic Research and as editor of the Journal of Economic History.

North helped found two influential professional organizations: the Cliometric Society in 1983 and the International Society for New Institutional Economics (ISNIE) in the 1990s. The field of cliometrics, which applies quantitative methods and neoclassical economic theory to history, was at first controversial among traditional historians. North followed the 1991 Nobel Laureate Ronald Coase as the second president of ISNIE, which focuses scholarly attention on the role of institutions in economic development.

North shifted his focus away from insurance and toward American economic development in the mid-1950s. His research on the U.S. balance of payments, conducted under the auspices of the National Bureau of Economic Research in 1956 and 1957, formed the basis for his first two books on the history of the American economy.

North's first studies of institutions assumed that institutions—which he defines as “formal rules,” “informal norms,” and “enforcement characteristics” that define a society's property rights—are efficient. His research on Western ascendancy, however, showed him that narrowly applied neoclassical economic theory, which also assumes efficient institutions, is an inadequate framework for understanding economic change. He thus spent the 1970s studying the emergence of inefficient institutions. This culminated in his influential 1981 book, Structure and Change in Economic History.

North's major contributions in the 1980s included estimates (with his student John Wallis) that an increasing share of the gross national product was devoted to the cost of transactions and research, suggesting that changes in institutions and property rights may lead to economic growth. North refined his theory, and in 1989 he published an influential study in which he and coauthor Barry Weingast argued that certain institutional arrangements may solve what is called the “sovereign debt problem.” First analyzed by Jeremy Bulow and Kenneth Rogoff, this problem suggests that any state strong enough to win a war is quite likely strong enough to renege on its promises (including loans), while any state so weak that it cannot successfully renege is also unlikely to last. North and Weingast showed how institutional change emanating from the Glorious Revolution of 1688 provided a partial solution to this problem.

In 1990 North published one of his most influential studies, Institutions, Institutional Change, and Economic Performance, which offered "a political-economic framework to explore long-run institutional change." This contribution began to explicitly incorporate questions of...
culture and ideology into a more general social-scientific framework.

North’s ideas have attracted a certain amount of criticism. For example, one of his most important works, *The Rise of the Western World* (coauthored with Robert P. Thomas), was criticized for basing a theory of institutional change on a Malthusian model in which resource scarcity leads to alternative bargains for property rights. His ideas have endured, however, and they continue to shape research in economic history and development. The breadth of North’s influence is perhaps most apparent through the distinctive mark it has left on widely cited research in development economics. North continues to push the frontiers of social science in his quest to understand why some people are rich and other people are poor, and it is perhaps most appropriate to close with a quote from his prologue to a 1997 collection of essays published in his honor:

> We still have a long way to go. I believe that an understanding of how people make choices, under what conditions the rationality postulate is a useful tool, and how individuals make choices under conditions of uncertainty and ambiguity are fundamental issues that we must address in order to make further progress in the social sciences. But we are making progress. (*Frontiers of the New Institutional Economics* 1997)

**NORTH AMERICAN FREE TRADE AGREEMENT**

On January 1, 1994, the North American Free Trade Agreement (NAFTA) went into effect, creating the largest free-trade area in the world. Many view NAFTA as a major policy victory for the architects of a new era of trade liberalization and economic globalization. Yet proponents of this view did not go unchallenged. NAFTA’s departure from several traditional trade concerns opened political opportunities for challengers to ally across borders and overcome longstanding political divisions, making it the most contentious trade policy initiative to date (Dreiling 2001).

**NAFTA AS A POLITICAL AND ECONOMIC PROCESS**

At the most explicit level, NAFTA is a treaty designed to liberalize trade and investment activity in North America. The trade agreement sets timetables for significant reductions in duties and a steady elimination of tariffs between
the three trading partners (Canada, the United States, and Mexico). Partly as a result of these reduced transaction costs, trade between the three countries has increased significantly. According to International Monetary Fund (IMF) data, the three NAFTA countries traded over $620 billion in goods and services in 2004, nearly doubling total trade volume in the ten years since NAFTA was implemented. Combined, the three countries produced over $12 trillion in goods and services in 2004 and, with more than 425 million people, constitute a major economic bloc in the world economy.

Literature on globalization portrays NAFTA as one of three distinct trading blocs in the world economy (Dicken 2003). The concentration of trade flows studied by sociologists, geographers, and economists reveals a growing tri-polar configuration of world trade relations and policy agendas of leading states. This research suggests that NAFTA and the Maastricht Treaty on European Union (1992) were driven by global economic forces as well as strategic political responses to globalization. NAFTA, seen from this perspective, reflects a trade-policy response to the regionalization of capitalist competition at a global level. Content rule, tariff reduction schedules, and other NAFTA provisions are designed to favor North American capital. Premised on an improved capacity to export commodities produced under low-cost conditions in Mexico into the high-price consumer markets of North America, western Europe, and Japan, NAFTA is an attempt to reclaim economic power in a capitalist world system. James Petras and Morris Morley argue that “NAFTA is the centerpiece of a new economic strategy … which Washington hopes to use as a springboard for its reemergence as a more competitive player in the world market” (1995, pp. 128–129).

During the debate over NAFTA, considerable attention was addressed to the question of “jobs.” Ross Perot’s presidential bid and famous claim of an impending “giant sucking sound” helped frame the political debate, but also alluded to important economic trends in all three countries. Prior to the conclusion of NAFTA, a steady erosion in manufacturing employment in the United States, coupled with a rapid increase of manufacturing employment by U.S. multinational corporations operating in Mexico, aroused fears of a decline of American industrial supremacy. Economists, such as Robert Blecker and William Spriggs (1992), showed how these patterns would likely continue with NAFTA, particularly in the maquila sector. The maquiladoras—literally meaning “twin plants”—generally refer to export industries along the U.S.-Mexico border, though the term is also used in reference to export processing industries in El Salvador, Guatemala, and elsewhere in Central America. After NAFTA’s ratification, the increase in manufacturing employment in Mexico by U.S. multinationals certainly did not create a “giant sucking sound,” but the movement of industrial-sector jobs has continued.

In a policy context, NAFTA represents an economic integration plan that extended the deregulation and free-market agendas of governments in the United States, Canada, and Mexico. Administrations under presidents Ronald Reagan and George H. W. Bush in the United States, Prime Minister Brian Mulroney in Canada, and President Carlos Salinas in Mexico initiated national reform agendas where market principles supplanted other institutional goals and organization. Known as neoliberalism—where market forces are believed to be the most efficient and least costly mechanism for allocating all societal goods—this ideological context all but guaranteed a free-market approach to North American integration. In this way, NAFTA emerged as a neoliberal counterpart to Europe’s more social democratic Maastricht Treaty.

NAFTA extends and accelerates market deregulation and trade liberalization efforts across the continent by creating supranational institutions and binding agreements between signatory governments. For example, one feature of NAFTA contained in Chapter Eleven prevents governments from discriminating against cross-border investors—all North American capital is to be treated as domestic capital, eventually. These provisions also establish an investor-state arbitration system that permits companies from one NAFTA country to seek monetary damages for actions or policies of another NAFTA government (national, state/provincial, or local). One oft-cited case began in 1997 when the Ethyl Corporation, a U.S. company, challenged Canada’s environmental ban of a known carcinogenic gasoline additive, methylcyclopentadienyl manganese tricarbonyl (MMT)—a chemical made by Ethyl. In July 1998 the arbitration panel ruled against Canada, forcing Canada to reverse its environmental ban on MMT and pay $13 million in damages and legal fees to Ethyl. As of 2005, five Chapter Eleven cases have settled in favor of investors, leaving critics wary of NAFTA’s bias in favor of capital at the expense of national sovereignty and environmental protection. From an analytical standpoint, the neoliberal framework of NAFTA helps investor rights trump environmental or national rights.

Neoliberal defenders of NAFTA, and free markets more generally, praise this “deepening and widening” of markets in the hemisphere, calling for an extension of NAFTA to Central America and throughout the Western Hemisphere as envisioned in the Free Trade Area of the Americas. Elaborate hemispheric plans for subregional and continental integration are discussed among elite policy organizations, from the Council on Foreign Relations to the highly influential Business Roundtable (Dreiling 2001). May 2005 discussions by elite supporters of
NAFTA alluded to a new “security perimeter” around North America, known as the North American Initiative.

THE IMPACT OF NAFTA
Migration from Mexico to the United States has risen significantly under NAFTA. Growing rural unemployment in Mexico and the instability of small farming in Mexico stem in part from NAFTA’s liberalization of trade in agricultural goods. With cheaper corn and grains imported from Canada and the United States into Mexico, small, often indigenous farmers are hurt economically. Worries persist that these pressures will also hurt peasant communities throughout Central America with the adoption of the Dominican Republic-Central America Free Trade Agreement in 2005. While pressure to migrate has increased, anti-immigrant politics persist in the United States, and the number of people found dead along the U.S.-Mexico border rose to a peak in 2003. Other U.S.-Mexico border problems were compounded by NAFTA. Mexico’s environment and urban infrastructure remain inadequate to support the growing population and heavy concentrations of export-oriented industry. The number of labor-intensive, export-processing factories along the border in Mexico increased by about 73 percent between 1993 and 2000, putting strain on both the environment and the mostly female workforce in those factories.

The expectation that greater wealth and income growth in Mexico would increase political pressures to limit environmental pollution remains unrealized. Arguments that refer to the environmental Kuznets curve—that pollution increases with per capita gross domestic product (GDP) at lower levels of national income while pollution decreases with per capita GDP at higher levels of national income—suggest that increased trade, and hence increased wealth pollution, will decrease in Mexico (Grossman and Krueger 1993). More research is needed to address this important question about the relationship between trade, economic growth, and political pressure to improve and enforce environmental regulations in Mexico and elsewhere.

Perhaps the most significant impact of NAFTA flowed not from the agreement itself, but the conflicts that arose in NAFTA’s wake. NAFTA, like its close relative and successor, the World Trade Organization (WTO), significantly departed from the direction of previous multilateral trade initiatives and inadvertently opened political opportunities for challengers to question neoliberal trade policy. Advancing new language on investment protections, institutionalizing language and protocols for protecting trade related intellectual property rights (TRIPs), and promoting a series of policy shocks to liberalize trade in agriculture, NAFTA drew a line that subsequent conflicts over trade policy would brave. These three concerns remain pivotal dividing lines within the WTO and in the ongoing discussions for a Free Trade Area of the Americas. Confrontations over patents on seeds and other “intellectual property,” non-tariff agricultural subsidies in richer countries, and investment rules have, for example, stalled agendas at the WTO ministerial meetings in Seattle in 1999 and in Cancun, Mexico, in 2003. NAFTA anticipated and promulgated these same divisions, prompting conflict both prior to and following its implementation.

The conflict over NAFTA catalyzed a mobilization of forces for and against the agreement. For over two years, the NAFTA negotiations faced challenges and changes, from a legal decision at a U.S. district court that required an environmental impact statement on NAFTA (which was subsequently appealed and overruled) to negotiations for two-side agreements on labor and the environment. Critics nearly stopped the passage of NAFTA. By the time that NAFTA went public in 1991, a broad spectrum of groups—from farmers to human rights organizations—began meeting to develop both national and international strategies to stop NAFTA in its tracks. Three years later, voices against NAFTA had developed a transnational movement, providing a supportive, if not encouraging, backdrop for the armed insurgency in Chiapas, Mexico, that initiated its mobilization with deliberate intent on January 1, 1994, NAFTA’s birthday.

Beyond the contentious interests mobilized for and against NAFTA, the agreement and the historical stage it set caught the eye of scholars. NAFTA, at a social scientific level, came to represent a triumph of markets, a continentalization of economies, and a window into the political struggles over globalization. As Jeremy Brecher and Tim Costello argued (1998), this neoliberal “globalization from above”—via free trade and corporate-sponsored multilateral institutions—is being resisted not only by “older” nationalist and protectionist foes of free trade, but also by a “globalization from below.” NAFTA helped set this stage.

NORTH AND SOUTH, THE (GLOBAL)
The terms the North and the South, when used in a global context, are alternative designations for “developed” and “developing” countries. Together, the North and South constitute virtually the entire global population. As terms, the North and the South emerged during the 1970s, probably simultaneously, and in contrast with each other. This article thus discusses these two terms together.

While the countries that make up the North and the countries that comprise the South share broadly similar economic and historical characteristics with the other countries in their category, there is no precise definition of either term. Two generations ago, the North could have been approximately defined as Europe and its offshoots (such as Canada, the United States, Australia, and New Zealand), but Japan has also, clearly, been a developed country for many years. Several other East Asian countries, including Singapore, South Korea, and Taiwan have shifted into the North in recent decades. While there are no recent examples of countries that have moved in the opposite direction (i.e., to the South from the North), the economic position of Argentina shifted from being one of the richest countries in the world, a century ago, to its middle-ranked position today.

Precise categorization is difficult for several contemporary nations, such as Russia and Saudi Arabia. Russia was recently admitted to the G-8 (previously the G-7), whose other members (the United States, Canada, France, Germany, Italy, the U.K., and Japan) are the richest and most economically powerful nations on earth. In contrast, Russia has a comparatively low life expectancy, which has fallen in recent decades. It also has limited political freedom and transparency in comparison to most countries in the G-8, and the North more generally.

The North and South have other names. No name is perfect, and neither the North nor the South is geographically precise. Several countries in the South are entirely in the Northern hemisphere (e.g., India, Nigeria), while Australia and New Zealand, each in the geographic South, are part of the global North, as evidenced by their longstanding membership of the Organisation for Economic Co-operation and Development (OECD). Such geographic imprecision is not unique. For example, the West (another synonym for developed countries) now includes Japan, as well as Australasia.

As terms, the North (also called the First World) and the South emerged during the 1970s in recognition of the greater economic and political power of the Third World, and in reaction to growing dissatisfaction with earlier terms, which were increasingly seen as pejorative. (This is discussed further below.) Although the South has long been home for the majority of the global population, its fraction of the global population is rising, as fertility rates have declined by a greater amount in the North. Reflecting this, the South is now sometimes called the majority world.

THE ORIGINS OF THE THIRD WORLD CONCEPT
In 1940 Colin Clark published “Conditions of Economic Progress,” which showed the world to be, as one reviewer commented, “a wretchedly poor place.” Two centuries earlier, almost the whole world had been “wretchedly poor,” and it is unlikely that the concept of “developing countries” would then have been much appreciated. The world had largely been divided into several empires, each of which possessed a “civilized” center and peripheries that were more or less considered primitive or even “barbaric.” Before the 1940s it is unlikely that the citizens of what would later be described as the North would have given much thought to the inhabitants of what was to become known as the South. When they did, most would have considered these peoples to be inferior in some way, by virtue of being non-white, less educated, or even “primitive.” Many people in the Third World were subjects in European colonies, living far from the global sources of economic, political, and military power. It is even less likely that the subjugated inhabitants of these Third World lands, many of whom were illiterate, would have
been aware that, even then, they formed a substantial part of the world population.

But such an awareness was growing among leaders within these poor countries, many of whom had been educated, at least partly, in Europe or America. This awareness and exposure to Western culture raised expectations and hopes, and inspired many Third World leaders to try to improve colonial living conditions and win political independence. Opposition to domination by the First World was also fed by increasing migration and travel, which had been stimulated by the two World Wars. Many troops who had participated in these wars, particularly on the allied side, were from the South. In addition, many Europeans served in Asia, and their exposure to conditions in the colonies probably helped erode the resolve of the colonial powers to keep their empires unbroken.

As the twentieth century progressed, the global decolonization movement strengthened, empowered by each country that achieved independence. An increasing number of countries in the South developed a national identity. The newly formed United Nations, born in the period of comparative hope and idealism that briefly flowered following World War II (1939–1945), also provided a forum for developing countries to share ideas and to argue their position before a wider audience.

The term the Third World was coined in 1952 by the French demographer, anthropologist, and economic historian Alfred Sauvy, who compared it with the Third Estate, a concept that emerged in the context of the French Revolution. (First Estate refers to the clergy and the monarch, Second Estate to the nobility, and Third Estate to the balance of the eighteenth-century French population—as much as 98 percent.) The Third World, as a phrase, also achieved acceptance because it usefully contrasted the poor countries to the First World (the non-Communist, high-income, “developed” countries) and the Second World (Communist countries, which though not as wealthy as those of the First World, were then characterized by greater order, higher incomes, and longer life expectancies.)

The decades that followed saw many attempts to form coalitions of Third World countries, to counter the vastly superior power of the “developed” First World countries. With hindsight, it is clear that these were only partly successful.

In 1955 Egypt, Indonesia, Burma, and the three powers of the Indian subcontinent (India, Pakistan, and Sri Lanka) organized the Asian-African Conference, held in Bandung, Indonesia. Twenty-nine countries, representing over half the world’s population, sent delegates—including the charismatic Chinese premier, Zhou Enlai—to Bandung. At this meeting, Indian Prime Minister Jawaharlal Nehru explicitly rejected both sides in the ongoing cold war between the United States and the USSR, expanding on the principles of non-alignment, a term he is credited with coining and first using in 1954. The meeting led to the development of the Non-Aligned Movement (NAM), which held its first formal meeting in 1961. Five charismatic Third World leaders—Nehru, Yugoslavia’s Marshal Tito, Indonesia’s Sukarno, Egypt’s Gamal Abdel Nasser, and Ghana’s Kwame Nkrumah—are credited with its establishment. China, despite its Communist ideology, has also been a member of the NAM at times.

In 1960, parallel to these developments, five other developing countries (Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela) founded the Organisation of Petroleum Exporting Countries (OPEC), at the Baghdad Conference. Soon after, OPEC was enlarged to include Nigeria and several smaller and poorer African states. Indonesia, the only NAM founder with substantial oil reserves, also joined OPEC.

In 1964 another coalition of developing nations was formed, called the Group of 77. India was instrumental in the formation of this group, which was also joined by Brazil, the most populous and economically powerful South American country and never part of the Non-Aligned Movement. The Group of 77 now has over 130 members. Although the People’s Republic of China has never been a formal member, it has been loosely affiliated since the 1970s.

THE EMERGENCE OF THE TERM THE SOUTH

The 1970s was a period of foment in the developing countries. Many improvements in living standards and life expectancy rates had been achieved in the 1950s, but by the 1970s these advances were stalling. Impatience in the Third World was growing. In 1973 OPEC substantially raised the price of oil, triggering the first global oil crisis. This had a major adverse economic effect upon the non-oil-exporting countries of the Third World, and revealed a lack of solidarity within the Third World overall. Parallel to this, the developed countries (prior to the discovery and development of the North Sea oil fields) were becoming increasingly dependent on the Third World for energy, due to the decline of U.S. oil reserves. These factors increased the economic power of part of the Third World. In 1974 the first UN-hosted population mega-conference was held in Bucharest. At this meeting the Group of 77 refused to accept responsibility for their poverty, instead blaming colonialism and ongoing Western exploitation. Famously, the Indian delegation called development “the best contraceptive.” This rebellious spirit was also reflected in calls from the Third World for a New International Economic Order (NIEO).
It is unlikely to be coincidental that the terms the South and the North were first widely used around this time. These terms appear to have entered common usage as an alternative to the long-standing geographical and cultural partition of the world into West and East. The new names avoided the stigma associated with the term the Third World, and created the hope that a new world order—one in which the North would be fairer to the South—was underway.

REASONS FOR THE PERSISTENT DISADVANTAGE OF THE SOUTH

However, new terms alone were insufficient to bring about fundamental change. Despite the aspirations and efforts of many people, in both South and North, most of the population of the South remains terribly poor. The reasons for this are complex, but several important interlocking factors can be identified. They include the South's historical legacy of disadvantage, much of it stemming from the colonial system. Also significant are the economic and development costs associated with enduring and fighting various diseases, especially malaria, tuberculosis, and HIV/AIDS, all of which affect a substantial number of adults, who would otherwise be more productive. High levels of Southern indebtedness, poor governance, and corruption are also important causes.

Other factors warrant mention as well. One is the comparatively high fertility rate in most developing countries, especially those that are the poorest. This leads to a proportionately large number of children and young adults, many of whom are poorly educated, un- or underemployed, and vulnerable to disease and economic exploitation. Another point is that, on the whole, populations and governments in the North have shown little interest in the social and economic fate of the South. For example, while for several decades many countries in the North have pledged to increase development aid to the South, very few large countries (and none of the members of the G-7) have followed through on these promises. In fact, Northern countries have behaved collectively as though it is just and proper that the economic and social privileges of Northern populations be enhanced by Southern poverty.

Also significant is the great diversity of the countries of the South. They are united by comparative disadvantage and poverty, but divided by differences in culture, language, religion, fertility rates, and stocks of oil and other natural resources. The two most populous nations in the South—China and India—have fought two wars with each other, and have had a continuous border dispute since the early 1960s. India is a secular democracy, which aspires to be a permanent member of the UN Security Council, a status long granted to its great rival China. Totalitarian China for its part seems as preoccupied with Russia and the United States as with the issues of the South. The South has also been divided by the policies of OPEC, a cartel whose richest countries have shown little interest in promoting the broader interest of the South.

NORTH ATLANTIC TREATY ORGANIZATION

The North Atlantic Treaty Organization (NATO) is one of the longest-running alliances in history. It has been one of the fixed points in international relations since 1949.
and is the most influential of the regional security organizations sanctioned under the United Nations Charter (Article 51). While to most casual observers it is a military arrangement, its founders’ prime purpose was political. They intended the alliance to provide an appearance of collectivity and strength that would both deter the enemy (the Soviet Union) and strengthen the determination of individual members to resist Soviet subversive infiltration. Members retain national control of armed forces but are prepared to submit them to command by foreign supreme commanders and command organizations manned by foreigners, and cooperate closely on usually sensitive issues such as security and intelligence.

The Essentially intergovernmental nature of the alliance means that such military cooperation necessitates a high level of political cooperation. The central forum for this is the North Atlantic Council (NAC). The NAC is staffed by permanent ambassadorial representatives. It is chaired by the secretary-general, who acts as the spokesman for the alliance and is effectively its chief executive. The essentially intergovernmental nature of NATO is maintained by twice-yearly meetings of foreign ministers. These meetings make the large policy decisions, which the secretary-general is then required to implement, with the NAC acting as a channel of communication. Since 1952 the NAC has developed permanent and ad hoc subcommittees dealing with a range of issues. The most important is the Military Committee, whose relation to the NAC is a little anomalous in that while it reports to the NAC, it is also directed by biennial meetings of NATO defense ministers. In addition, sitting atop the whole structure are summits of heads of government when deemed necessary.

The North Atlantic Treaty (signed in Washington, D.C., on April 4, 1949) pledged that an attack on one of the twelve signatories—the United States, Canada, Iceland, Denmark, Norway, Belgium, Netherlands, Luxembourg, France, Britain, Portugal, and Italy—was an attack on all and would lead them to take whatever measures they deemed necessary, including armed action. Effectively it placed the European members under American nuclear protection. While military planners were initially skeptical of the defensive capabilities of the alliance, for the politicians the main point was to increase the Western European sense of security.

The emphasis changed during the early 1950s as a result of the Korean War. With the fear that Korea would quickly be followed by a Soviet attack in Germany, the overtly military aspect of the alliance was moved to the foreground, where it was to remain until the cold war ended. Supreme Headquarters, Allied Powers Europe (SHAPE) was established in 1951 in France. NATO has three commands, Atlantic, English Channel, and Europe, but the commander of Europe (SACEUR) is the senior. Greece and Turkey, which had been under NATO guarantees, became members in 1952. Most significantly, West Germany was admitted in 1955 and was allowed to contribute forces under the command of the West European Union.

NATO’s function and structure came under scrutiny in the 1960s. Some in the United States believed that since Western Europe had recovered economically, it should shoulder a greater share of its own defense. American advocacy of “flexible response” also caused problems with the allies, who feared the expense of competing with the Soviets in conventional forces and who felt the American nuclear guarantee was being compromised. Moreover, French president Charles de Gaulle saw NATO as an instrument of Anglo-American hegemony, and in 1966 France left NATO’s military structures. NATO headquarters had to relocate to Belgium.

Against the background of these developments, the Belgian foreign minister produced the Harmel Report, The Future Tasks of the Alliance (1967). While committing NATO to engage actively in the process of détente—reducing tensions with the Warsaw Pact—it also stated firmly that NATO was an organization serving the security needs of its members rather than a purely defensive military alliance whose existence was dependent on a specific threat.

Détente gave way to increased tension during the early 1980s, and NATO deployed intermediate-range nuclear weapons (INF) and cruise missiles in some European countries. Relations between NATO and the Warsaw Pact warmed once Mikhail Gorbachev came to power in the USSR, and in December 1987 the United States and the USSR agreed to eliminate all land-based INF missiles.

In 1982 NATO added its sixteenth member with the accession of newly democratic Spain. In 1990 the reunification of Germany moved NATO’s frontiers significantly eastward. In 1991 the Soviet Union ceased to exist, and some in the West felt that NATO should follow suit, arguing it no longer had a purpose. However, NATO supporters were able to point to the Harmel Report and depict NATO as an organization to promote general security through stability and collective action. At Rome in 1991 a new Strategic Concept declared that instability was often caused by the activities of nationalist or terrorist groups. The North Atlantic Cooperation Council was set up, with sixteen NATO countries and nine others, becoming in 1997 the European Atlantic Partnership Council with forty members (forty-six by 2001). At Brussels in 1994 the Partnership for Peace was formed to promote defense cooperation.

The first test of the reality of NATO’s ability to manage instability in Europe was the long crisis as Yugoslavia
disintegrated. NATO proved to be hesitant and divided. It was not until 1997 that the implications of NATO’s new role were properly addressed, using the forum of the Partnership for Peace. NATO began to make significant contributions to UN peacekeeping efforts, beginning with missions to the former Yugoslav republics. The partnership also made possible the NATO-Russia Founding Act signed in Paris in 1997, establishing the NATO-Russia Permanent Joint Council (PJC). This reduced Russian hostility to NATO expansion, easing the accession of Poland, Hungary, and the Czech Republic in 1999. Through the PJC, Russian troops took part in peacekeeping forces in Bosnia. Tensions remained with the Russians, especially when the crisis flared up in Kosovo in 1999 and the Russians remained cautious about NATO’s role.

There was a show of solidarity by NATO members after the September 2001 terrorist attacks on the United States, but this was undermined by the unilateralism of the Bush administration. NATO did agree to operate out of area—for the first time—taking control in August 2003 of the International Security Assistance Force in Afghanistan, following American and British operations against the Taliban. Germany and France, however, disliked Bush’s approach and opposed the attack on Iraq in 2003. This became a NATO issue when they vetoed American requests to strengthen Turkey in advance of the attack. Pessimists predicted NATO’s immediate demise. The solidity of NATO’s permanent structures, however, meant that it survived this crisis. Thus, although as an intergovernmental alliance it had become somewhat dysfunctional, ironically, its extensive multilateral structures proved a binding force; if only out of inertia and the practical difficulties of untangling integrated military structures, especially regarding intelligence. Indeed, NATO continued to expand, with seven new members joining formally in 2004—Bulgaria, Estonia, Lithuania, Latvia, Romania, Slovakia, and Slovenia.

NORTH-SOUTH MODELS

The large difference in the levels of economic development between the countries has made many view the world as being divided between the rich North and the poor South. North-South models divide the world economy along these lines and examine the interaction of the two regions through trade and other economic relationships.

The classical economists, including Adam Smith (who discussed the importance of increasing productivity due to the division of labor as economies grew) and David Ricardo (who examined the role of trade in postponing the arrival of the stationary state in rich countries by enabling cheap food imports and in having the opposite effect for poor countries), discussed North-South issues. Subsequently, Marxist writers on imperialism and dependency theorists, and development economists more generally, stressed the role of the South in providing markets and investment outlets for the North, and examined the problems of surplus transfers from the South, the deterioration of the southern terms of trade, and of uneven development.

MODELS WITH STRUCTURAL ASYMMETRIES

More mathematically explicit North-South models emerged from the early 1980s. In a 1980 article for the American Economic Review, Ronald Findlay examined capital accumulation in a global economy with the North growing with full employment and the South with unlimited supplies of labor at a fixed real wage. In 1983 Lance Taylor allowed for unemployment in the North as well, assuming that effective demand determines northern growth. These and other models can be thought of as special cases of a general framework, in which the northern good is a consumption-cum-investment good, and the South a consumption good. The models embody specific behavioral and institutional assumptions for the North and the South, thereby highlighting their structural differences. They have been used to examine the effects of changes in such things as technology, consumption expenditure patterns, and savings rates. Of particular interest are results which demonstrate that southern growth depends on northern growth (which is determined inde-
pendently of the South), the relationship between the southern terms of trade and southern growth, and the possibility of uneven development (reflected by a rise in the relative size of the North) due, for instance, to technological change and changes in consumer preferences. Some of these mechanisms of uneven development have been endogenized to model processes of cumulative causation due to factors such as the income-inelastic demand for southern products, international demonstration effects, and endogenous technological change, as expressed in Amitava Krishna Dutt’s book Growth, Distribution, and Uneven Development (1990). These results confirm some of the informal ideas of earlier writers on uneven development, but they depend on some of the specific assumptions made about the structures of the northern and southern economies.

The basic trade models have also been extended in several directions. For instance, international capital movements from the North to the South in search of higher profits have been shown to exacerbate uneven development, due to a fall in the price of the southern good because of increases in southern production, and to profit repatriation to the North, although under certain circumstances foreign direct investment, by making possible the production of the northern good in the South, can result in greater North-South equality.

The models stressing structural asymmetries between the North and the South do not explain why such asymmetries arise. Implicitly they assume that events in the past, such as the Atlantic slave trade or colonial domination, create and lock in these structural differences. Models which assume identical structures for the two regions have also been developed to show how small historical events can make one region (the North) end up exporting manufactured goods exhibiting increasing returns to scale, while the other region (the South) becomes more agriculturally oriented, so that there is uneven development.

**NEOCLASSICAL MODELS**

The models discussed so far can be seen as reactions to the dominant neoclassical Heckscher-Ohlin-Samuelson (HOS) trade models, which contain optimizing agents, are usually static in nature, and assume that markets clear so that labor and other resources are fully employed everywhere. However, the neoclassical approach has also contributed to the development of North-South models. For instance, environmental factors have been introduced into them to examine how stricter pollution control in the North can lead to a movement of “dirty” industries to the South, thereby exacerbating southern environmental problems, as seen in Brian Copeland and Scott Taylor’s 1994 article for the Quarterly Journal of Economics. Most of the North-South models from the neoclassical perspective, however, have followed the contributions of new growth theory, which emphasize the role of increasing returns and externalities in the growth process; this can be seen, for example, in William A. Darity and Lewis S. Davis’s 2005 article for the Cambridge Journal of Economics.

Many new growth theory models imply economic divergence between rich and poor countries due to economies of scale along Smithian lines even without any interaction between the two. These results often carry over to models with North-South trade. For instance, trade can increase (reduce) the wage of skilled labor, the abundant factor in the North (South), thereby increasing (reducing) the incentives for education, labor productivity, and growth. This is not a necessary outcome, however; the increase in the wage of skilled labor may slow down research and development and hence technological change and growth in the North and increase it in the South.

Neoclassical models have also been used for examining North-South technology transfers. It may be supposed that if knowledge is something that all countries can share, the South will eventually catch up to the North. However, those who have studied the process of technology transfer recognize that it is not very easy to transfer technology and it requires southern countries to build up technological capability to be able to learn from, and adapt to, foreign technology. Moreover, the protection of international property rights (IPR) can serve as a barrier to technology transfers. The protection of IPR has been a major source of conflict between the North and the South, and it has been claimed that the lack of such protection will slow down innovation in the North and hence the world. A number of models, however, suggest that weaker protection of IPR will not only speed up technology transfers, but also accelerate innovation in the North as northern resources are devoted more to innovation activity than to production.

North-South models are useful for understanding the nature and consequences of the interaction between rich and poor countries, and to address key issues concerning international inequality and global growth. They can be criticized for downplaying the differences within rich and poor countries, and the possibility that poor countries may grow and join the ranks of the rich. However, two-region models have been extended to include a third, consisting of newly industrialized countries, to explore the causes of its growth and to analyze whether its growth results in the end of uneven development or the exacerbation of the gap between the rest of the South and the North.

NOUVEAUX RICHES

_Nouveaux Riches_ translates literally to “new rich,” and it refers to individuals or families who have recently risen to higher economic standing but have not gained full social acceptance by members of the established upper class or elite. While the nouveaux riches do possess substantial economic wealth, they are regarded as lacking the prerequisite cultural skills and dispositions to fully become members of society’s elite. To signify their membership in elite status groups, the nouveaux riches may mimic the cultural consumption of the established upper class; however, these efforts are often not entirely successful. Pierre Bourdieu in _Distinction_ (1984) describes the new bourgeoisie as possessing a similarly large degree of economic capital but less cultural capital relative to the old bourgeoisie.

The Industrial Revolution played an important role in the rise of the nouveaux riches, notably through the expansion of a highly educated, urban middle class with considerable time and resources for leisure activities. These upwardly mobile, wealthy individuals then worked to legitimize their elite status by adopting the styles and tastes of the established upper class.

For much of British history, for example, “old money” has been gentrified and titled, with large estates and hereditary seats in the House of Lords. The nouveaux riches mimicked the old aristocracy to an extent by buying estates and sending their children to the same elite boarding schools. However, they also developed their own, often indulgent, sense of style that was in contrast to the more refined sensibilities of the established elite (Crook 1999). In his critical analysis of the late-nineteenth-century American upper classes, Thorstein Veblen in _The Theory of the Leisure Class_ ([1899] 1932) finds that the nouveaux riches worked to emulate European aristocratic families by engaging in “conspicuous consumption.” However, they were considered by “old money” to lack taste, manners, and discretion:

> Many a gentleman of the old school has been provoked to remark regretfully upon the under-bred manners and bearing of even the better classes in the modern industrial communities; and the decay of the ceremonial code … among the industrial classes proper has become one of the chief enormities of latter-day civilization in the eyes of all persons of delicate sensibilities. (p. 46)

More recently, in the former Soviet republics a class of nouveaux riches emerged, largely composed of former Communist Party bureaucrats who made fortunes during the transition to market capitalism and privatization (Brucan 1998, pp. 69–94).

While in previous eras the nouveaux riches were considered to demonstrate a distinctive set of artistic tastes, attitudes toward culture, political views, and the like, it appears that many of these differences have reduced over time. As Max Weber in _Economy and Society_ ([1922] 1968) describes, while status groups do often draw on cultural attributes to achieve social closure and advance their own interests, ultimately “at some point economic conditions become causally important and often decisive” (p. 341). Over time, the common economic conditions and shared class interests of the new and old rich may serve to overcome social differences and create a unified elite class.

NURSERY RHYMES

Although popular collections of nursery rhymes were widespread from the eighteenth century on, and academic collections have been published since the nineteenth century, their academic study really began in the twentieth century. Several approaches have been taken by scholars over the past four or five generations, and these have been largely determined by the academic climate of their day. One such early tack was the expounding, or even invention, of a rhyme’s “history” trying to answer the question deriving from adult wonder about children’s lore: Where does it come from? Contemporary folklorists have been more likely to try to understand the meanings of folklore in use than to plumb its history; centuries of looking closely at the phenomena of folklore have taught them that folklore—including children’s rhymes—is so fluid and changeable, while by dint of its orality being so undocumented in the written record, that the search for its history can at best be quixotic.

The English term nursery rhyme covers a somewhat larger group of folklore than a simple reading of the term would suggest. Although many thus-categorized rhymes are indeed used in the nursery (that is, with children under, say, four years old as audience), a much larger number of them are used by adults with somewhat older children, by children themselves no matter their age, and by adults. Nonetheless, the term nursery rhyme has great utility and has been retained by most authors.

Twentieth-century approaches to nursery rhymes have included attempts to understand variation, to read rhymes as expressions of psychosexual maturation, to show how they introduce children to the tools of language and intellectual thought, and, most recently, to see them as agents of empowerment for children and vehicles of cultural conservation. All of these approaches have attracted many authors and have been fruitful.

Despite academic findings to the contrary, it has often been claimed that earlier generations’ nursery rhymes were “originally” coded messages about political events and historical eras. Such interpretations may be seen as the “folklore of folklore” and most often can be dismissed as modern euhemerism. (Euhemerus was a fourth-century BCE Greek who claimed that myths of the gods were actually transformed stories about real historical people.) Euhemerist traditions about nursery rhymes have circulated, especially in the educated classes, for a hundred years, floating around like migratory legends and—also like legends—localizing from time to time.

It is understandable that such interpretations arise. It is popularly known that much folklore is “old.” Interested and creative people look for ways to show how old it is. New folklore grows as easily as old folklore did, and now it finds itself an explanation of the older folklore. Folklore items have a text (their words or other formal shape), but they also often carry a more variable set of traditional beliefs and understandings as a kind of corona around the text. These secondary texts can take the form of localized legends explaining the “history” of the item.

The Humpty Dumpty rhyme is a good example of this process; in its euhemerist form, Humpty Dumpty has become a local legend in at least a half-dozen places, mainly in Great Britain. In Gloucester, Humpty Dumpty has come to represent a siege ramp built in 1643 by Charles I’s forces to cross the River Severn and take the city from Cromwell. But the ramp, according to the euhemerist tradition, collapsed under the cavalry’s weight:

Humpty Dumpty sat on the wall,
Humpty Dumpty had a great fall,
All the king’s horses and all the king’s men,
Couldn’t put Humpty together again.

Similar readings have been attached to, among others, the English kings James I, King John, and Richard III, the last because of his hunchback (= Humpty). Likewise “Pop Goes the Weasel” is interpreted as being about a piece of nineteenth-century textile equipment, or a cobbler’s bench. All folklore varies by text, and the different texts of this rhyme—“carpenter’s bench,” “vinegar bush,” “vinegar jug,” and so on—produce different euhemerist readings. One reading has it in a pawnbroker’s shop and provides a foundation legend for some
Salvation Army followers. Often the rhyme’s own words are given as examples of now-obsolete slang that seems to “prove” the truth of the legend. All of these readings are attempts by modern people to connect to historical figures that which would otherwise appear to be “mere” children’s nonsense. But modern texts are commonly used in these attempts to come up with “older” readings.

Interpretations sometimes have contemporary political undertones. In early 2000, in England, Birmingham’s city council banned “Baa Baa Black Sheep” from local schools because, the council said, “the history of the rhyme … is offensive to black people due to the fact it originates from slavery.” In fact, as the research by Peter and Iona Opie has shown, it is most likely not related to slavery, but simply an amusing, and largely nonsensical rhyme. Children, in any era, are amused by nonsense.

The euhemerist belief that “Ring around the Rosie” comes from one of the great plagues seems to have arisen in the 1960s, and was given greater weight by academic promulgations. The claim gained popularity in a 1961 biology textbook about rats and the plague, James Leasor’s The Plague and the Fire. Leasor did not consult folklorists but, based on folklore from his own relatives, assumed the rhyme was known centuries before it was. More recently, Norman Cantor, a historian of the plague, did the same in his In the Wake of the Plague (2001). There are two main regional forms of the rhyme: “Ring a Ring of Rosies,” which is mainly British, and “Ring around the Rosie,” which is mainly North American. The two traditions are not entirely separate; examination of historical texts shows a great deal of overlap. Kate Greenaway’s text (in her little book Mother Goose) was the first in print, appearing in Britain in 1881. William Wells Newell published a second version in North America several years later, in an academic collection of children’s rhymes. He said it dated back to the 1790s but he does not say who his informant was, or how he knew that fact. This is Newell’s “earliest” text, using the now-British form of the first line:

Ring a ring a rosie,
A bottle full of posie,
All the girls in our town
Ring for little Josie.

Newell included another more contemporary version, probably circulating in Massachusetts in the 1880s or 1890s:

Round the ring of roses,
Pots full of posies,
The one who stoops the last
Shall tell whom she loves the best.

This text represents very clearly a typical “forfeits” game with an “all fall in” section in the third line. The lack of plague references is apparent here, as in all the pre-twentieth century texts. Only in the mid-twentieth century do the “Ashes ashes” (or “A tissue!”) forms start to appear; such late texts are the “evidence” (clearly inadmissible) of being about the plague.

In the late twentieth and into the twenty-first century, the rhyme grew in symbolic value, giving a human face to plagues. HIV-AIDS groups in the United States used the rhyme to bring attention to the need for research into AIDS and support for HIV+ people. Rock musician Dave Matthews used it in his popular song “Gravedigger” to indicate how disillusioned a child is when she learns her childhood song is “about death.” In an interview in Rolling Stone in February 2004, he said, “It’s the classic of classics about dying.” Not just for activists and artists, it had become a symbol of plague, of death, disease, and the corruption of flesh.

Children’s folklore is a rich area for contemporary scholarly study partly because it continues to pick up traditions and generate symbols. But symbol is not history. The history of “Ring around the Rosie” is much shorter than the plague interpretation would have it. The symbols are modern, not “old,” folklore—but they also show nursery rhymes to be living, contemporary culture.

Nutrition

Nutrition is a vital physiologic process necessary for the development and maintenance of the human body, its organs, and its physiological processes. In order to maintain good health, individuals require daily intake of protein, fat, and carbohydrates—nutrients that provide energy, vitamins, minerals, and water. Nutrition provides necessary nutrients that are not produced by the body. The daily requirements of these nutrients vary depending on individuals’ age, sex, and physiologic state (that is, pregnancy).

In the United States dietary guidelines are updated every five years and are the basis for the Food Guide Pyramid. These guidelines are issued by the U.S. Department of Agriculture (USDA) and the U.S. Department of Health and Human Services (HHS). The Food Guide Pyramid groups foods into major categories (fruit, vegetable, dairy, grain, meat, and bean) and recommends serving sizes and the number of servings needed to achieve balanced nutrition and health. In 2005, to address the dramatic rise in obesity, the USDA modified the Food Guide Pyramid to emphasize lower energy intake and more physical activity and provide an individualized approach. The USDA promotes nutrition based on the fact that certain dietary patterns may place individuals at risk of chronic diseases, such as cardiovascular disease, diabetes, and cancer. Diets rich in saturated fat and low in fruits and vegetables are associated with heart disease, cancer, and diabetes, while diets rich in fruits and vegetables may protect individuals from these conditions.

The balance between energy intake and energy expenditure determines weight maintenance or weight gain and loss. When regular energy intake is greater than the expenditure, the body stores the surplus of energy as extra body fat or adipose tissue. Energy expenditure is a result of the basal metabolic rate, the thermic effect of food (energy spent in processing food), and the energy spent in physical activity. The contribution of physical activity to energy balance is small compared to food intake. Energy intake and dietary patterns are influenced by hormonal mechanisms and psychosocial factors. People eat in response to hunger signals that the body creates, such as changes in blood glucose levels. Hunger can also be experienced in response to sensory cues, such as the smell or sight of favorite foods.

Satiety is regulated by a complex hormonal signaling system with input from proteins secreted by the brain, the gastrointestinal tract, and the liver. In the brain the hypothalamus secretes small proteins called neuropeptides. The neuropeptides inhibit food intake after receiving input from hormones and proteins synthesized in the stomach and intestines. Ghrelin, which is synthesized predominantly by the stomach, stimulates feeding. In the fasting state ghrelin levels are high, and levels fall after eating. The intestine releases cholecystokinin (CCK) after a meal, which stimulates gut motility, the contractions of gastrointestinal muscles that enable food to move along the digestive tract and ensure absorption of nutrients and inhibits food intake by signals to the brain. Other organs and hormones are also involved in the regulation of food intake and satiety. After a meal, the pancreas secretes insulin, which in turn signals the brain to inhibit feeding. Leptin is a hormone synthesized in adipose (fat) cells, and its secretion is regulated by the obese (ob) gene. Leptin levels are low during starvation and high when nutrients are plentiful and in obesity. High levels of leptin signal the brain to reduce appetite. In obesity people are resistant to the effects of leptin. The hormone adiponectin is secreted by adipose cells, and its secretion is stimulated by food restriction. Adiponectin is also a factor that increases energy expenditure, and low levels may contribute to the development of obesity.

The body seems to tolerate positive energy balance, that is, when energy intake is higher than expenditure. The mechanisms described above strongly defend from weight loss but not from weight gain because of an evolutionary process that favored intake of nutrients when food was easily accessible and in preparation of times when food was scarce. This evolutionary perspective can explain in part the obesity epidemic that emerged during the last decades of the twentieth century when, in developed countries, there was abundance of food without periods of scarcity.

Nutrition is not only influenced by biological factors. Environment, culture, and social factors also play impor-
tant roles in nutrition. The environment determines the
type and quality of foods accessible to individuals and
communities. A diet rich in refined sugars, carbohydrates,
and fat is related to increased availability of fast foods, sug-
ared beverages, and low-nutritional value snacks and
decreased access to produce (fruits and vegetables). A pos-
itive energy balance in turn is caused by increasing calorie
intake, especially when reinforced with a sedentary
lifestyle. Social factors, such as low income and low socio-
economic status, are associated with less healthy dietary
patterns with higher saturated fat intake and lower intake
of fruits and vegetables possibly due to the facts that low-
income individuals are more likely to live in communities
with less access to healthy foods and that healthier food
items are proportionally more expensive that unhealthy
ones. Industrialized societies eat a diet rich in meat and
saturated fat and lower in fiber compared to agrarian soci-
eties, who consume more fruits, vegetables, and grains.
Research indicates that immigration changes dietary pat-
terns of individuals, who over time adopt the diet of their
host country.

In people with excess weight, a diet restricting calo-
ries but maintaining balanced nutrient composition can
achieve healthy weight loss and reduce the risk of diabetes
and cardiovascular disease, which are conditions associ-
ated with obesity. However, when the calorie restriction is
severe and the diet does not allow for sufficient amounts
of essential nutrients, dieting can lead to metabolic and
heart problems and even death. The psychological factors
that are associated with nutrition are best exemplified by
obesity and eating disorders. Obese individuals frequently
have low self-esteem and depression. Whether these are
causes or consequences of obesity is still under debate.
Some individuals may increase their food intake in
response to feelings of stress, loneliness, and anxiety,
which place them at risk of overweight and obesity. Eating
disorders include anorexia, characterized by being severely
underweight from excessive food intake restriction, and
bulimia, characterized by purging. Either disorder may
also have periods of binge eating. Eating disorders, espe-
cially anorexia, are associated with body image dissatisfac-
tion, depression, and low self-esteem.

NUYORICANS

The term Nuyorican refers to Puerto Ricans born or raised
in New York City, or more broadly in the mainland
United States, as distinguished from those from the
island of Puerto Rico. Indeed, the word in a range of
other spellings—“neorrican,” “neerrriqueno,” and
“newyorquino,” among others—was first used by those
from the island, notably in the glossary of Guillermo
Corto-Thorn's early novel about Puerto Rican life in
New York, Trópico en Manhattan (1952) and, in more
direct anticipation of the usage familiar today, in Jaime
Carrero’s long poem NeoRican Jetliner (1965). But in
those early, island-based occurrences the term often car-
rried a derogatory or at least derisive connotation. It sig-
nified cultural inauthenticity and evoked a paternalistic
sympathy for the cultural loss, or even blame for the
betrayal involved in the migrants’ adaptation to North
America. It also could imply significantly negative quali-
ties in terms of class (usually very poor and lazy), some-
times described with the idea of “lumpen” (proletarian),
and race (generally identified as black, perhaps tainted
with the proximity of African Americans). Many were the
young New York Puerto Ricans who experienced painful
rejection and discrimination on occasions of their tem-
porary or permanent return to their ancestral homeland,
especially in the 1970s and more recent decades.

Nuyorican in its present spelling and usage emerged
in the early 1970s in part as a reaction to this negative
characterization. The founding of the Nuyorican Poets’
Café on New York’s Lower East Side in 1973 and the pub-
lication of the anthology Nuyorican Poetry in 1975 were
the major events in this historical emergence, in both cases
resulting from the collaboration between writers Miguel
Algarín and Miguel Piñero. But it was rapidly adopted by
many other writers, artists, and other New York–born
youth of Puerto Rican extraction. It became the name of
a vibrant poetic and artistic movement of those vibrant
years of ethnic awakening, capturing as it did the zeitgeist of the Puerto Rican community in the 1960s and early 1970s, and featuring such poetic talents as Victor Hernández Cruz, Sandra María Estevez, and the quintessential Nuyorican poet Pedro Pietri. Algarín and Piñero both recount the indignities they endured at the hands of members of the island’s cultural elite, and how they then took the negative term and threw it back at them with a sense of cultural pride, much as African Americans did in those same years with the word black. A dramatization of this act of resignifying occurs in the more recent film Piñero (2002), in a vivid scene depicting Piñero’s encounter with that elite on his visit to the island in the mid-1970s. Though another Loisaida (Lower East Side) cultural institution of the times, the New Rican Village, may be considered an even more significant center of experimental expression in those same years, it was the word Nuyorican spelled in that idiosyncratic way that has continued as the identifying cultural nomenclature for subsequent generations of Puerto Ricans in the U.S. diaspora. In its combination of Spanish and English phonetics, its semantic mix of “newness” and geographical location, and its intertwining of the New York and the “Rican” reference, that spelling has turned out to be ideally appropriate to epitomize a fully hybrid, bicultural field of personal and group identity, corresponding to the term Chicano among Mexican American youth of the same period.

In more recent times some objections to the usage have emerged because of the dispersal of U.S.-based Puerto Ricans and the emergence of significant communities in other places, notably Philadelphia, Chicago, Florida, and other cities in the Northeast such as Hartford, Connecticut; Jersey City, New Jersey; and Springfield, Massachusetts. Though no new word has arisen to replace the geographically specific Nuyorican, some writers and others have toyed with such neologisms as diasporican and AmericaRican, the latter a signature poem by well-known writer Tato Laviera. Terms clearly modeled after Nuyorican, such as ChicagoRican and PhillyRican, have also cropped up, as has nomenclature such as Dominican Yorks and MexYorkers to name newer Latino groups in New York City. In more recent times, change is also evident even in Puerto Rico, where the concept first emerged in its less sanguine usage: The diaspora cultural experience has gained greater acceptance, receiving frequent coverage in the media and cultural institutions, though often still in reluctant or paternalistic terms. Among the youth on the island, many of whom are from families of return migrants who were raised on the mainland, Nuyorican has come to be a term of strong admiration and even emulation. Significantly, Old San Juan now boasts the Nuyorican Café among its cultural nightspots. In the days of hip hop, reggaetón, and spoken-word poetry, the long-standing gap between island and diaspora cultural realities has finally come to narrow, and the ironic, deeper meaning of the highly charged expression Nuyorican to come full turn.

NYERERE, JULIUS

1922–1999

Julius Kambarage Nyerere, the first president of the East African country of Tanzania, was born on April 13, 1922, in a town called Butiama, located on the eastern shore of Victoria Falls. His father, Nyerere Burito, was the chief of the Zanaki tribe and had twenty-five other children. Being raised in such a large family allowed Julius to experience directly the benefits and costs of “communal living”—an idea later made central to his political philosophy. Life in such a family structure also affected the development of his educational philosophy, in which Nyerere sought to combine the epistemologies of Africa and Europe. From Europe, where he studied at Edinburgh University, Nyerere absorbed the socialism of the British Fabians. From Africa, where he combined his early communal life with a Catholic primary school education, Nyerere developed a philosophy not unlike that of the American William James in terms of an emphasis on pragmatics. These experiences constituted the foundation of his personal philosophy, perhaps best epitomized in the pamphlet “Development is for Man, by Man, and of Man” (1978): “Man does not develop himself in a vacuum, in isolation from his society and his environment. And he certainly cannot be developed by others. Man’s consciousness is developed in the process of thinking, and deciding, and acting. His capacity is developed in the process of doing things.”

Nyerere thus challenged the idea that a scholar should not get involved in the practical affairs of politics. As a com-
mitted activist, he had a number of critics, both European and African. The former were upset because Nyerere was a leader of the African liberation movement that sought to remove the injustices inherent in the British colonial system. The latter were upset because they feared that Nyerere was an example of yet another African whose body was in Africa but whose mind was conditioned in Europe and whose ultimate loyalties were therefore suspect.

Nyerere's political decisions were not, however, entirely predictable. He was not an ideologue, although he was an unabashed socialist and his plans for land redistribution did not endear him to Western powers. His support of the overthrow of Uganda's President Idi Amin was condemned by many African political observers as a cave-in to the demands of the American/Israeli interests rather than African interests. Yet the decision was cheered by the European/Western press, which described it as a noble act of gratitude for foreign economic assistance to Tanzania. The same set of observers winced when Nyerere offered unconditional support for the armed struggle to free Southern Africa. Some observers have minimized this militaristic side of Nyerere's presidential reign and have instead focused on his pragmatic embodiment of the non-violent spirit of India's Mahatma Gandhi.

The Gandhian influence was also reflected in Nyerere's support of the unification of the offshore island of Zanzibar with the mainland, as well as in other personal efforts of reconciliation between the East Indian immigrants and the indigenous African communities.

Nyerere did not take his African constituency for granted. He championed the incorporation of the local language, Kiswahili, into every facet of Tanzanian life. One legacy of that decision is the appearance of the Kiswahili language in the widely celebrated holiday of Kwanza among African Americans in the United States today.

Like many other post-independence leaders, Nyerere's exposure to Western education was both a blessing and a curse. Its blessings were evident in that it equipped him with the skills necessary to negotiate the treacherous waters of independence from Britain, and a curse because it sometimes tied him too closely with the oppressors of his people.

Nyerere's handling of the ever-present duality was reflected in his early support of both the Commonwealth (of former British colonies) and the OAU (Organization of African Unity). The support of both required a considerable degree of deftness because the organizations' goals were often incompatible. Such political deftness earned Nyerere the respect and admiration of many world leaders. His decision, in 1985, to relinquish the presidency and to retire to his farm for a life of reflection and international peace-making activities—a role later played by South Africa's first president, Nelson Mandela—further enhanced his international reputation.

South African leader Nelson Mandela was one of several future leaders whom Nyerere nurtured as president of Tanzania. Robert Mugabe, whose own efforts at land redistribution resembled Nyerere's, was another who was given refuge as a leader in the liberation struggle of Southern Africa.

Julius Nyerere died in London on October 14, 1999, after a short battle with leukemia. He left behind a wife and seven children and a well-deserved legacy befitting the title Mwalimu (teacher).

1944–

Ronald Oaxaca is the McClelland Professor of Economics and faculty associate at the Economics Science Laboratory at the University of Arizona. Best known to many economists as the developer of the Oaxaca wage decomposition technique for examining wage differentials, he has conducted research and published extensively since the 1970s on topics such as labor economics, applied econometrics, and applied microeconomics including sex, union, and race differentials and discrimination; unemployment and unemployment insurance; and the minimum wage.

Oaxaca is perhaps best known for developing one of the most important methods used in the field of labor economics to study wage discrimination based on sex and race known as the wage gap decomposition, which he outlined in his 1973 article “Male-Female Wage Differentials in Urban Labor Markets.” Also influenced by economist Alan S. Blinder, the wage gap decomposition provides a means for identifying residual differences between observed and predicted wages that are not accounted for by characteristics associated with productivity, such as education and skill, and can thus be attributed to labor market discrimination and other omitted variables. The seminal method has since been refined and elaborated upon to add other elements of analysis, such as the use of alternative wage structures as reference points for comparison; selectivity bias; comparative analysis across countries and time; the explanation of penalties associated with motherhood; and analysis of discrimination across the income distribution rather than using means. Oaxaca has also continued to utilize and improve upon the wage decomposition, notably with Michael R. Ransom in two studies conducted in 1994 and 1999 (as mentioned in Yana van der Meulen Rodgers’s 2006 article “A Primer on Wage Gap Decompositions in the Analysis of Labor Market Discrimination”), further refining methods for developing the nondiscriminatory wage structure and emphasizing the importance of the reference group for estimating the unexplained or discriminatory portion of the wage gap.

More recently Oaxaca has focused on topics such as the influences of ability and family background on optimal schooling levels; the effects of dual job holding; statistical discrimination; and consistent estimators of linear probability models. His continued study of gender differentials in wages includes work to examine the impact of technology and to compare trends in the United States and Denmark. Further he is conducting research on such disparate subjects as determinants of faculty salaries, the production of engineering degrees, optimal sick pay schemes, gender bias in the criminal justice system, and measurement error in work experience. He currently serves as the coeditor of American Economic Review, and he is on the editorial board of the Journal of Economic Inequality. From 1986 to 1989 he was on the editorial board of the Journal of Urban Economics, and he previously coedited Economic Inquiry. To date he has published over seventy articles, working papers, and book reviews.

Oaxaca is also a teacher who has been a member of over seventy thesis committees since 1978. He joined the faculty of the University of Arizona in 1976 (after teaching at the University of Massachusetts from 1973 to 1976) and has been a visiting professor at a number of institutions, including Smith College (1975); Princeton...
University (1982); Stanford University (1983–1984); New Mexico State University (1991), where he was a Distinguished Visiting Professor; the University of Aarhus in Denmark (1997); and ERMES at the University of Paris II (2003). He is an active member of the Association for Hispanic Economists.

Oaxaca was a fellow of the Udall Center at the University of Arizona from 1995 to 1996 and since 2001 has been a research fellow at the Institute for the Study of Labor (IZA) in Bonn, Germany. In 2005 Hispanic Business magazine selected Oaxaca to appear on the list of the 100 most influential Hispanics.

Oaxaca earned a bachelor’s of science (summa cum laude with honors) from California State University at Fresno (1965) and a master’s (1969) and doctorate (1971) in economics from Princeton University.

OBEDIENCE, DESTRUCTIVE

Obedience is the act of compliance to the commands of a legitimate authority. In destructive obedience the acquiescence is to a command to harm another person. The phrase was first introduced into the social sciences in 1963 by Stanley Milgram in his article “Behavioral Study of Obedience” in the Journal of Abnormal and Social Psychology describing the first of a series of experiments on obedience he conducted at Yale University from 1961 to 1962.

In those experiments the subject was told to teach a learner a series of word pairs, using increasingly painful electric shocks—up to 450 volts—as punishment for each error. Although the shocks were fake and the learner was an actor who feigned his suffering, the experiment was stressful for most of the subjects. Sixty-five percent of the subjects were fully obedient to the experimenter’s commands, progressing to the maximum shock. The unexpectedly high rate of destructive obedience was the central and most dramatic finding in Milgram’s experiments. While we did not need Milgram to tell us that people tend to obey authorities, the sheer power of that finding was revelatory: that ordinary people would act contrary to conscience and hurt an innocent person at the bidding of an authority without coercive means to enforce his or her commands.

Milgram conducted over twenty different variations in his series of experiments on destructive obedience. A second important insight is provided by a subset of those variations. In that series Milgram varied the distance between the teacher and the learner. As the distance was reduced, so was the percentage of obedient subjects. The morality of shocking an innocent victim did not change from condition to condition, but the tendency to obey the destructive orders did, demonstrating that the immediate situation can have powerful effects on behavior even at the expense of the subject’s personal inclinations.

Milgram undertook his research to shed light on the Holocaust in an attempt to explain how normal people could become complicit in carrying out the murderous commands of Nazi leaders. Although early twenty-first century regulations in the United States and other countries make it virtually impossible to replicate Milgram’s experiments, experiences in real life continue to affirm his findings.

For example, in 2004 two male students at a Georgia high school obeyed their teacher’s orders to throw an unruly female classmate out the window. Real-life events also have broadened the scope of destructive obedience in several ways. For instance, it is known that destructive obedience can take place even when the self is the victim. A review of airplane accidents between 1978 and 1990 found that in about 25 percent of cases the first officer’s reluctance to correct an error made by his or her captain was a contributing factor. Also the power of destructive obedience when the action is damaging in a nonphysical manner is as strong as or stronger than is the case when the obedient act is physically destructive, strong enough to override a person’s moral or ethical principles. As a teaching exercise, a University of San Diego law professor, Steven Hartwell, had his students advise a client on how best to present her side of a rent dispute in court. Hartwell told them to advise the client to lie under oath and say that she had paid her rent. Twenty-three of twenty-four subjects complied and told the woman to perjure herself.

OBESITE EXTERNALITY

In the late 1960s, the social psychologist Stanley Schachter (1922–1997) proposed that obese people eat (and overeat) not because of hunger, stress, or boredom, but in response to external (i.e., environmental) food cues, which drive eating in the obese until those cues are removed (or consumed). External food cues include the sight or smell of palatable food and other salient cues in the situation indicating that eating is appropriate. When external cues are absent, the obese are not motivated to eat, even if they are substantially food-deprived. This focus on internal and external cues is often seen as originating in Schachter's earlier research on emotion, although a close reading reveals significant differences in Schachter's analyses of these two domains.

Schachter's obese-externality theory achieved widespread attention because it challenged long-standing ideas about the causes of obesity by means of several innovative and dramatic experiments. These experiments showed that obese people's food intake is less affected by manipulations of food deprivation and distress than is that of normal-weight people. Obese individuals, for instance, are less disturbed by time-zone changes or by the requirements of religious fasting, as long as food cues are not prominent. These clever studies, written with great flair, were complemented by studies demonstrating that obese people are differentially affected by manipulations of external cues, ranging from varying the visual prominence of food cues (by, for example, altering the lighting or providing nuts either shelled or unshelled) to doctoring a clock (so that dinnertime arrived either early or late) to offering experimental subjects either one or three sandwiches to eat. These studies fascinated the research community, even if the data were not always robust.

Schachter's research was correlational, showing that obesity is associated with externality. He assumed that externality (in an environment rife with food cues) causes obesity. But what is the source of externality? Schachter postulated that impairment of the brain's ventromedial hypothalamus (VMH) was responsible; rats with VMH damage behaviorally resemble obese humans. This line of reasoning was extended by Schachter's student Richard Nisbett (1972), who argued that suppression of VMH functioning was a consequence of weight suppression by dieting or other means, which is common among the obese. This proposal led in turn to research by C. Peter Herman and Janet Polivy (1980) on restrained eating (dieting), which hinged on the notion that even normal-weight people who suppress their weight ought to be especially external. Work on restrained eating, however, quickly turned away from questions of internal versus external. The Eating Disorders Inventory contains a scale concerned with interoception, the perception of one's own internal states, which is weak in those with eating disorders; but again, the eating disorders literature pays scant attention to Schachter's internal/external distinction.

Challenges to the obese-externality theory include the argument that internal and external cues reciprocally influence each other and are thus inseparable. Research shows that external cues (such as social influence and portion size) exert such a powerful influence on food intake in everyone that it is misleading to identify external responsiveness exclusively with the obese. Still, Schachter's original proposal has not been disproved so much as superseded by subsequent formulations, all of which owe a debt to his groundbreaking demonstrations of how eating may be studied experimentally and creatively.

**OBESITY**

Obesity results from chronic energy intake that exceeds energy expenditure and is characterized by "excessive" body fat. The precise assessment of an individual's body fat is an expensive and complicated procedure. Instead, body mass index (BMI), though somewhat controversial, is used commonly because it is easy to assess and correlates highly with body fat. BMI is calculated by taking an individual's weight in kilograms and dividing it by that individual's height in meters squared (kg/m²). For adults a healthy BMI is between 18.5 and 24.9. A BMI of 25 to 29 is classified as overweight, obesity is defined as a BMI of 30 to 39, and clinically severe obesity is defined as a BMI of 40 or more. Because of the pervasive social stigma associated with the term obesity, it is avoided for children; at risk for overweight and overweight are the recommended terms. To account for normal age and sex differences in children's body fat, at risk for overweight is defined as a BMI at or above the 85th percentile and overweight as a BMI at or above the 95th percentile of the sex-specific BMI-for-age growth charts.

**PREVALENCE OF OBESITY**

Health statistics for the United States reveal a dramatic upsurge in obesity prevalence during the early 1980s, and the rates have continued to rise. U.S. national health statistics in 2007 estimated that 34.1 percent of adults were overweight, 32.2 percent obese, and 4.8 percent clinically obese; 17.1 percent of children and adolescents age six to nineteen were estimated to be overweight, and 16.5 percent were at risk for overweight. Sociodemographic risk factors for obesity include being of a racial/ethnic minority and being of low socioeconomic status.

**CONSEQUENCES OF OBESITY**

Obesity is associated with high morbidity and mortality rates. The medical sequelae of obesity include type II diabetes, coronary heart disease, stroke, osteoarthritis, sleep apnea, and some cancers, including breast and colon cancer.

Among the most insidious and common adverse effects are the socioemotional consequences of obesity. Obese individuals are significantly more likely to experience social stigmatization and discrimination in all domains, including education, employment, social relationships, and health care. Also, obesity is associated with low self-esteem, body image disorders, anxiety, and depression. Associations between BMI and body satisfaction vary with race/ethnicity and gender. African Americans have a higher mean BMI than do European Americans but tend also to have greater body satisfaction. Generally, females report significantly lower body satisfaction than do males regardless of race/ethnicity.

**ENVIRONMENTAL EXPLANATIONS**

The escalating rates of obesity since the 1980s are attributable to a complex interaction of environmental, sociocultural, behavioral, and biological/genetic factors that is not well understood. At a macrosystemic level, U.S. food policy is fundamentally at odds with the goal of healthful eating. Food is overproduced, and as a result of the abundant supply, food companies must compete aggressively for market share. Cheap, palatable, and accessible energy-dense foods are mass-marketed and offered in portions vastly disproportionate to individuals' caloric needs. A marked shift toward away-from-home and prepared food consumption probably has resulted from time constraints caused by a rise in dual-career and single-parent working families. In 1977, 9.6 percent of meals were eaten at restaurants and fast food outlets; by 1996 that proportion had risen to 23.5 percent.

Over roughly the same period consumption of high-fructose corn syrup (HFCS) increased 1000 percent or more. HFCS is used instead of sugar (glucose) as a caloric sweetener in many foods and all soft drinks; however, it is digested, absorbed, and metabolized differently than glucose is. Fructose, unlike glucose, distorts levels of insulin, leptin, and ghrelin, the hormones that act as key signals in food regulatory processes and body weight, making dietary fructose a prime suspect in the obesity epidemic.

A sedentary lifestyle is an important contributing factor, especially in light of the fact that decreased energy expenditure has been accompanied by increased energy consumption. A sedentary lifestyle is a natural consequence of a built environment characterized by urban sprawl that necessitates travel by car or mass transit and time-consuming commutes. Technological advancement that reduces energy output, low-energy office occupations, and leisure preferences such as television viewing and computer use increase the probability of a physically inactive lifestyle.

**EARLY PSYCHOLOGICAL THEORIES**

Two classic psychological theories of obesity predate the onset of the obesity epidemic. To explain differences in the eating patterns of obese and normal-weight individuals, in 1968 Stanley Schacter proposed the internal-external theory of obesity and in 1972 Richard Nesbitt proposed the set point theory. Schacter hypothesized that obese individuals are more likely to be responsive to cues from the external environment such as the sight and palatability of food, whereas normal-weight individuals are more likely to eat in response to internal physiological cues. Nesbitt countered with the hypothesis that each individual has a unique, biologically determined ideal weight, with obese individuals having an above-average set point. He theorized further that societal ideals of thinness
cause obese individuals to restrain their intake and eat below their set points, essentially causing a chronic state of deprivation and hyperresponsiveness to external food cues. These models of obesity have faded in importance because of a lack of empirical support. However, the derivative construct of dietary restraint and its effect on individuals’ eating patterns continues to generate much research and some controversy.

DIETARY RESTRAINT

Dietary restraint is defined as the deliberate and persistent restriction of food to promote weight loss. Restraint theory proposes that restrained eaters may develop disordered eating patterns as a result of the stress inherent in chronic appetitive self-control. Although research has supported a relationship between dietary restraint and disinhibited eating, the validity of the restraint measurement scales is at issue and further work on more definitive construct measurement and the role of dietary restraint in disordered eating is warranted.

BIOLOGICAL EXPLANATIONS

Obesity also is explained by reference to biological processes. Research indicates that neuroendocrinological processes, most centrally the hypothalamic-pituitary-adrenal (HPA) axis, figure prominently in obesity. The HPA axis, which consists of the hypothalamus and the pituitary and adrenal glands, is a key player in stress regulation as well as in physiological processes such as digestion, energy use, and mood. Stress, which is inherent in the daily demands of the twenty-first-century environment, causes elevated cortisol secretion by the HPA axis. Protracted stimulation of the HPA axis results in a flood of neuroendocrine-endocrine disturbances that in turn cause insulin resistance and visceral (abdominal) obesity. Visceral obesity carries the highest risk for comorbidities.

Genetic research is still in its early stages. There is substantial heritability of individual differences in BMI. However, more than twenty genes, hypothesized as working in conjunction with a wide range of environmental factors, have been linked to obesity. Clearly, obesity is causally very complex. Equally clearly, however, obesity is an urgent health problem that will continue to be a challenge for the foreseeable future.

OBJECT-RELATIONS THEORY

SEE Psychoanalytic Theory.

OBJECTIVE FUNCTION

In an optimization problem, there is a (real-valued) function that is to be maximized or minimized. This function is frequently called the objective function, a term that seems to have arisen in the realm of planning and programming, particularly linear programming, through the work of mathematician George Dantzig (1914–2005). Prior to 1947, when Dantzig invented the linear programming problem and the simplex method for its solution, military logistical plans, called “programs,” involved large-scale decision-making based on ground rules. Dantzig created mathematical models to capture the conditions that needed to be satisfied and a criterion for choosing one feasible solution over another. This made a significant contri-
bution to a vital sphere of activity. Dantzig ushered in a new era in decision-making and brought forth the term objective function as a numerical mathematical expression for the objective that was to be achieved by the program.

Thus, an objective function measures the “goodness” of a feasible vector, that is, a vector whose coordinates satisfy all the imposed side conditions, if any. To illustrate, in a linear programming problem,

\[
\begin{align*}
\text{maximize} & \quad \sum_{i=1}^{n} p_i x_i \\
\text{subject to} & \quad \sum_{i=1}^{n} a_{ij} x_i \leq b_j, \quad j = 1, 2, \ldots, m
\end{align*}
\]

the objective function is the linear form \( \sum_{i=1}^{n} p_i x_i \) which might, for instance, measure the total revenue resulting from sales in the amounts \( x_1, x_2, \ldots, x_n \) at unit prices \( p_1, p_2, \ldots, p_n \). The inequalities in this illustration represent side conditions (or constraints) on the variables \( x_1, x_2, \ldots, x_n \).

This is not to say that all objective functions (or all constraints) are of this type. They may be linear or nonlinear, depending on how goodness is defined in the applied context. The function being minimized in a parameter estimation by the “least-squares” criterion is an example of a nonlinear (actually quadratic) objective function. In problems of this sort, the “variables” in question may be “free” (unconstrained) or constrained. In the nonlinear case, convexity (or lack of it) becomes an important issue from the optimization-theoretic standpoint.

The underlying concept of an objective function—under a different name or no name at all—had existed for centuries before Dantzig introduced this particular terminology. One has only to recall the method of multipliers devised by Joseph-Louis Lagrange (1736–1813) for equality-constrained optimization problems. Many synonymous terms are in use. Among the more abstract ones are maximand for maximization problems and minimand for minimization problems. These terms can be used in the respective optimization problems no matter what the application may be. In applied areas such as econometrics, one finds the term criterion function. Still others with an obvious connection to economics are social welfare function, economic welfare function, loss function, and profit function. Further examples coming from other fields are distance function and flow value, the point being that the term used in place of objective function might refer to what it is measuring.

**OBJECTIVE VALUE**

**SEE** Value, Objective.

**OBJECTIVISM**

Objectivism is the philosophy enunciated by the Russian-born American novelist and philosopher, Ayn Rand (1905–1982).

Rand’s philosophical system begins with a realist premise: Reality is what it is, independent of what people think or feel. The concept of “objectivity” is central to Rand’s theory of knowledge. A knowing subject can acquire objective knowledge of reality only through reason, a distinctively human faculty, which integrates the inductive evidence of the senses, in accordance with logical principles.
Because reason is a basic means of acquiring human knowledge and, hence, a basic tool of human survival, Rand places it at the center of her conception of ethics. In Rand's view, reason enables human beings to discover those principles and practices necessary to their sustenance as rational animals. Rand's ethical egoism proclaims the "virtue of selfishness," that it is morally right for individuals to pursue their own rational self-interests, voluntarily exchanging spiritual and material values.

Rand argues that the only social system consonant with this "trader principle" is laissez-faire capitalism, wherein individuals constitute free-market relationships. These relationships depend upon a structure of individual rights to life, liberty, property, and the pursuit of happiness. Rights can only be violated, Rand maintains, if an individual or group of individuals initiates force against others.

Rand supports a libertarian nonaggression principle that allows for the retaliatory use of force against those who initiate it. This principle informs Rand's defense of government as an institution with a monopoly on such retaliatory uses. In keeping with a classical liberal or libertarian conception of politics, Rand restricts government institutions to the role of defending individual rights, through the police, the armed forces, and the judiciary.

RAND'S LIFE AND WORK
That such a defender of capitalism and limited government was born and raised in Russia during the period in which the Bolsheviks came to power is ironic. Rand would publicly reject what she saw as the mysticism of Russia's religious culture and the collectivism and statism of its politics. But some scholars have argued that aspects of her approach to philosophical and social problems echo some of her early Russian influences. Born Alissa Zinovievna Rosenbaum in Saint Petersburg to a middle-class family, Rand witnessed a reign of Communist terror that led her to a virulent rejection of totalitarianism in all its forms. She was educated, however, during a cultural period known as the Russian Silver Age. Central to Silver Age thought, and to Rand's thought as well, is a rejection of conventional dichotomies: mind versus body, fact versus value, theory versus practice, and so forth. During this period, the influence of Friedrich Nietzsche (1844–1900) was also substantial; Nietzsche's writings had a significant effect on the young Rand's early thinking. Having graduated from the University of Leningrad in 1924, Rand had been exposed additionally to the teachings of prominent professors in both the dialectical idealist and Marxist traditions—those who emphasized, like Rand, the importance of grasping the full context of any problem as a prerequisite to its resolution.

In 1926 Rand immigrated to the United States, fully committed to pursuing a career as a writer. Her first novel, *We the Living* (1936), details communism's violent subjugation of social life. Rand said that this novel was as close to an autobiography as she would ever write. Its focus is on the individual versus the state, that is, how an oppressive state ultimately creates an "airtight" environment that must destroy individual human lives. The novel was later adapted by Italian filmmakers, who produced an unauthorized, though largely faithful, film version during World War II (1939–1945).

Rand also wrote a novella called *Anthem* (1938) that projects a primitive collectivist society of the future in which personal pronouns—and independent thinking—are prohibited. Despite that society's best efforts to stamp out individual identity, the protagonist (known as Equality 7-2521) rediscovers the "I" and, in so doing, heralds the rebirth of individualism.

In *The Fountainhead* (1943), Rand tells the story of architect Howard Roark, a trader, entrepreneur, and creator, who is a man of integrity struggling mightily against the collectivist culture and statist politics of the age. The novel enabled Rand to explore the soul of the individualist, those qualities of rationality, productiveness, independence, and authenticity that are essential to people's survival and flourishing. Adapted for the screen in 1949, directed by King Vidor (1894–1982), and starring Gary Cooper (1901–1961) as Roark, the novel was Rand's first major commercial success.

But it was in *Atlas Shrugged* (1957) that Rand first presented the philosophy of objectivism. With three parts named after the Aristotelian laws of logic—it was Aristotle (384–322 BCE) whom Rand credited as having had the greatest impact on her thought—the novel is an epic mystery, part science fiction, part fantasy. With the world on the verge of collapse, strangled by political interference with economic and social life, the productive "men of the mind" go on strike. By refusing to sanction their own victimization, and by withdrawing from the world, the strikers bring down the system of exploitation. It is only with their return to the world that a free society becomes possible.

In this novel, Rand presents her image of ideal men and women, people who are "new intellectuals," men and women of thought, who are also men and women of action. Such individuals reject the mind-body dichotomy and all of its insidious consequences—reason versus emotion, thought versus action, morality versus prudence—which fragment human existence.

This stand on the integrated individual also underlies much of the work that Rand wrote during her years as a public philosopher. Her nonfiction works, such as *The Virtue of Selfishness* (1964) and *Capitalism: The Unknown
Ideal (1966), repudiate all modernist “false alternatives,” including idealism versus materialism, rationalism versus empiricism, religious conservatism versus welfare liberalism, fascism versus communism, anarchism versus statism, and so forth. Though her political stance is libertarian, insofar as it rejects any government intervention in the economy or in people’s personal lives, Rand was profoundly critical of contemporary libertarianism because many of its adherents focused on economics without regard for the larger philosophic and cultural context that would nourish the triumph of human freedom. In Rand’s view, though human freedom entails free trade, it can only be fully achieved when people are free to think and to act on the basis of their own rational, independent judgment. This requires their psychological and moral liberation from exploitative ideologies that demand human sacrifice. As Rand argues in For the New Intellectual (1961), “intellectual freedom cannot exist without political freedom; political freedom cannot exist without economic freedom; a free mind and a free market are corollaries” (p. 25).

OBJECTIVITY

Objectivity in the sciences, especially the social sciences, is paired implicitly or explicitly with its opposite, subjectivity. Less obvious yet commonplace pairings with the term objectivity are partiality, relativity, and the arbitrary. This entry deals primarily with objectivity in opposition to subjectivity. Subjectivity is associated with the modern concept of the self. The shift to the notion of the modern self occurred concurrently with the scientific revolution of the seventeenth century.

DESCARTES AND HIS CRITICS

René Descartes (1596–1650), who is considered the father of modern philosophy, claimed to be able to doubt systematically the existence of anything except the fact that he was doubting. Because doubt is a species of thought, he asserted, “cogito ergo sum,” which usually is translated as “I think therefore I am” or “I think therefore I exist.” Even Descartes’s body did not survive his systematic doubt; only his mind—“a thinking substance”—did. He argued that upon this rationally defended certainty rested all other claims regarding the existence of objects outside the mind. In that absolute divide the mindful inside became the subjective state and anything on which the mind exercised its cognitive power was an object. Thus, objectivity came to refer on the one hand to the subject’s ability to consider or represent external objects without being influenced by subjective feelings, opinions, or prejudices and on the other hand to the description of those mind-independent objects. Despite Descartes’s many detractors, modern philosophy made bringing subjective thought into concordance with objects of external reality its signal challenge.

Descartes’s critics in his day and soon afterward could be divided into two camps: the idealists and the empiricists. Despite their differences, they held in common with Descartes the idea that the senses play a part in objectivity. The idealists described sensation variously as a species of thought but one that is unclear and indistinct, inferior, and unreliable or merely as confused thinking. Among those critics were Benedict Spinoza (1632–1677) and Gottfried Wilhelm Leibniz (1646–1716).

Conversely, British empiricists reinstated the sensory perception of objects in experience as the source of all reliable knowledge and the basis of objectivity. Thomas Hobbes (1588–1679) described thought as merely the faint remains left behind by sense impressions, and John Locke (1632–1704) argued that all ideas about the external world arise from sensation and reflection; if not for the sensory input made available by the senses in experience, the mind would be a blank tablet. For David Hume (1711–1776) thought was nothing but the faint copies of “impressions” left behind by the senses. In Hume’s under-
standing, claims to objectivity are based not on reason but on habits of expectation that are developed from accumulated sense experiences.

CRITICAL PHILOSOPHY

The response to the early British empiricists can be seen as twofold: critical philosophy on one hand and the philosophy of science on the other. The origin of critical philosophy most commonly is identified with Immanuel Kant (1724–1804). Kant did not see objectivity-subjectivity as a proportionately inverse relation. They were distinct, and so one could not be considered an inferior form of the other or vice versa even though only together could they make objectivity possible.

Kant’s concept of the object, however, was very subtle, and he used three different terms for it: Ding, Gegenstand, and Objekte. Ding referred to the metaphysical thing-hood, as in ding an sich, the unknowable thing in itself, making the question of objectivity moot. For even minimal experience to be possible, the contents of experience (“sensory data”) must be ordered and limited in certain ways. These ways are not determined by what is given to the senses but by the synthetic activity of the faculty of intuition that possesses certain principles of form—space and time—that constitute the synthetic unity of sensory apperception. For what is given is, as Hume held, nothing but a flux of sensations and images. The synthesis of this manifold of sensory data is an a priori and necessary feature of experience and not empirical. This object of appearance that is experienced in this synthesis is the Gegenstand. The Gegenstand, this experience of appearance as object, is only a re-presentation. It is transformed into an object of recognition, understanding, and thereby it becomes an objekt. Kant described the objekt as “that in the concept—of the understanding—of which the manifold of a given intuition is united.” (Kant [1787] 1965, p. B137). It is this objekt of knowledge about which the subject of the experience can make judgments that are true or false. By objectivity, then, Kant meant the object of a true judgment. However, this is not the judgment of an individual subject but that of a transcendental subject.

In the triumvirate of the great sociologists of the nineteenth and early twentieth century, Max Weber (1864–1920) is the most (neo-) Kantian of the three.

PHILOSOPHY OF SCIENCE

Whereas critical philosophy was a reaction to British empiricism, the philosophy of science was its progeny. Among the many strands in the history of the philosophy of science, positivism has been the most conspicuous. Auguste Comte (1798–1857), who invented the term positivism, was an admirer of Hume and with Hume held that there is no objectivity beyond human objectivity. However, unlike Hume, he did not begin with an empiricist account of the contents of the mind but instead with a history of human development. According to that history, inquiry begins with theology, which is transformed into metaphysics, which is replaced by positive science.

For Comte objective science and observational science were near synonyms. Science, he held, should restrict itself to the observation of appearances and stop looking for or speculating about hidden “causes.” He believed that hypotheses must be based only on phenomena that can be grasped by the cognitive and sensory faculties and be open to positive verification; this alone could guarantee objectivity. Comte saw the social world as unified with the physical and subject to laws that were identifiable by natural observation, hence sociology, the science of society. Émile Durkheim (1857–1917), the French sociologist and precursor of structuralism, considered his sociology to be in the positivist tradition and antipathetic to Kantian metaphysics, which nevertheless saturated his most important work, The Elementary Forms of the Religious Life.

In the twentieth century the prioritization of the sensory was channeled into logical positivism with its focus on language and logic. In logical positivism the objective world is considered a world not of things but of facts. Objectivity describes the capacity to express verifiable facts—the truth or falsity of which can be determined—in meaningful sentences. A meaningful sentence is seen as one that in some way can be related to a foundational sense experience or analytically true statements. Bertrand Russell (1872–1970) thought that he could derive the world from experience by means of symbolic logic. Rudolph Carnap (1891–1970) was determined to prove the world’s verifiability, even though Ludwig Wittgenstein’s (1889–1951) Tractatus clearly signaled the ultimate failure of that attempt. However, logical positivism persisted until it ran its course almost a decade before Carnap’s death in 1970.

Georg W. F. Hegel (1770–1831) led Kantian insights even further from empiricism. For Hegel, objectivity was a matter of degree and an integral part of knowledge in which the subject is confronted with two types of objects: the external thing it desires to know and its own consciousness. In the Phenomenology of Spirit ([1807] 1977) Hegel’s aim is to show that all claims to knowledge are best understood as historically and socioculturally situated. Empiricists hold that not only is objective knowledge—that is, knowledge that is independent of social practices—possible but that it is the only form of knowledge worthy of its name. The candidates that are proposed as being able to secure such knowledge, independent of any historically specific social practice, are “sense-cer-
Objectivity

tainty,” “perception,” and the “force of understanding,” in that order. Hegel demonstrates that all three fail to provide, on their own terms, the kind of knowledge that their proponents’ claim for them. In fact, under the “force of understanding” the reader is forced to acknowledge that it is our recognition of a thing that makes it real. But who is this subject that does the recognizing? While it is true that both Hegel and Kant presuppose a unified self or subject that is capable of knowing, for Kant such a self is a given, whereas for Hegel it is we who presuppose or construct this self. But how do we construct a self without recognizing it? This is where the “other” becomes necessary, for it is only the other who can recognize and construct one, and thereby makes one real. Moreover, the other must not take me to be a mere object of his or her self-consciousness but as a self-conscious knowing subject in my own right. It is at this point that Hegel uses his, by now famous, master-slave parable to begin the dialectical argument of why the objects of our knowledge are inter-subjectively and socioculturally constructed and known. Thus a reflective socialized and historicized self-consciousness works its way dialectically through reason and spirit, toward absolute knowledge in an ever-expanding and increasingly shared point of view that leads toward a universal point of view, which would at least theoretically serve as the standpoint from which pure objectivity, both moral and epistemological, would be possible.

Hegel was the first philosopher to historicize objectivity and chart its growth in the dialect of history. Unlike Kant, he did not base objectivity on the abstract analysis of its conditions but on the human sociohistorical subject. Even so, Karl Marx (1818–1883) accused him of positing a method of coming to know, which lost its way in the clouds of ideas and ideologies. If human history is to be seen in its reality, Marx claimed, it is necessary to look at human labor and relations of production and domination. This is the road to objectivity in history. Paradoxically, Marx may be considered to be the closest to Hegel among the great sociologists, even if the object and the objective are viewed materially rather than ideally by Marx.

OBJECTIVITY IN TWENTIETH-CENTURY PHILOSOPHY

The influence of Kant’s and Hegel’s understandings of objectivity are vast and varied, sometimes reemerging under different labels. In the pragmatism of the American philosopher Charles Peirce (1839–1914), Kantianism, Hegelianism, and British empiricism are modified and compounded. Here experiences are more than what the senses report; they include anything that is forced upon one’s acknowledgment, real or ideal, including sensory and cognitive surprises. Experiences are only perceptual judgments and therefore can be true or false but never infallible; they are authoritative only because people are compelled to accept them, if not in the short run, then in the long run.

For Peirce, the so-called outer and inner worlds are only vicinities with no boundaries. Therefore, neither metaphysical theses nor so-called analytic statements are immune from empirical evidence; their truth, and hence their objectivity, depends on their ordinary observable consequences, not on their experiential origins. A correspondence theorist of truth would hold that a proposition or belief is true only if it corresponds to a mind-independent reality and as a corollary would insist that a hypothesis can be true even when its truth has no consequences for belief. A pragmatist would hold that such a view, insofar as it has no consequences, is spurious. Objectivity must be connected with the hypothesis that will survive the test of inquiry, experiment, experience, and life. As for truth, it is nothing more than the best inquiry can do.

Inquiry must begin against a background of beliefs held with or derived from a community, and therefore its objectivity can be fixed only by a community of inquirers committed to its truth, a truth that is capable of having consequences. In Peirce’s theory of the Sign, the object is one of three correlates that constitute the Sign, the other two being the representamen and the interpretant. Objectivity is a significant act of which the interpretant (of which the interpreter is a subset) is an indispensable component.

The view of knowledge as human understanding that was initiated by Hegel’s dialectic of self-consciousness admitted “interpretation” into the human sciences in a major way. If in Edmond Husserl’s (1859–1938) early Cartesian writings there appeared aspects of sensory objects that an empiricist or positivist could have recognized as such, by the time he wrote his last work, The Crisis of European Sciences and Transcendental Phenomenology, consciousness had become his prime, if not sole, object of inquiry. In his phenomenology of human experience in the world Husserl saw no way of getting around the fact that consciousness is always someone’s consciousness, and so he proposed that the process of investigating human capacities and faculties had to begin with the rigorous self-examination of one’s self. Husserl called this the standpoint of transcendental solipsism. This methodological solipsism, however, leads one to the recognition of intersubjective communal grounding of the knowing activity as well as the ethical dimension of that intersubjectivity, how the “I” stands in the “we.” He came to see objectivity as the achievement of intersubjective confirmation and acceptance in the “life-world,” a pre-theoretically experienced world. The influence of Husserl’s phenomenology in sociology can be seen mainly in the writings of Alfred Schutz (1899–1959), who com-
bined that phenomenology with the interpretive sociology of Max Weber.

Among the philosophers considered thus far, objectivity was seen as possible because objects are re-cognizable. Heidegger, Dilthey, and later Gadamer became interested in understanding the unique and unrepeatable—and hence unre-cognizable—in history and culture. Wilhelm Dilthey (1833–1911) held fast to the possibility of scientific objectivity with the proviso that the method for achieving objectivity in the human sciences was different from that employed in the natural sciences. Both Weber and Dilthey had a strong influence on the interpretive anthropology of Clifford Geertz (1926–2006). Heidegger and Gadamer rejected the very notion of objectivity and the subject-object model as a vestige of Cartesianism. Hans-Georg Gadamer (1900–2002) saw understanding as an aesthetic experience of history and as being quite different from but no less valid than that of the natural sciences. Indeed, the natural sciences were no less value-free in his opinion and no less free of the art of interpretation.

**NIETZSCHE AND FOUCALT**

Friedrich Nietzsche (1844–1900) spoke about objectivity in a manner that was consonant with all the historical-hermeneutic sciences. He believed that to understand objectivity as a "contemplation without interest" was nonsensical and absurd. "[L]et us be on guard," he cautioned:

against the dangerous old fiction that posited a "pure, will-less, painless, timeless knowing subject"; let us be on guard against the snares of such contradictory concepts as "pure reason," "absolute spirit," "knowledge in itself." … There is only a perspective seeing, only a perspective "knowing"; and the more affects we allow to speak about a thing, the more eyes, different eyes, we can lend to the thing, the more complete will our "concept" of this thing, our "objectivity," be. But to eliminate the will altogether, to suspend each and every affect, supposing we were capable of this, what would that mean but to castrate the intellect. ([1887] 1967, p. 119)

In this view, if Hegel’s hope for an absolute knowing that could synthesize a range of perspectives must come to naught, the rejection of objectivity by Heidegger and others who employ the hermeneutic method is premature:

"Objectivity" [ought to be understood] as the ability to have one’s For and Against under control and to disengage them, so that one knows how to employ a variety of perspectives and affective interpretations in the service of knowledge. ([1887] 1967, p. 119)

Nietzsche’s subject is embodied and governed by desire and passion more than by thought, but it is still Cartesian in that it is the arbiter of being and value. Nietzsche’s influence has been especially strong in the writings of Michel Foucault (1926–1984).

OBOTE, APOLLO MILTON
1925–2005

Apollo Milton Obote became the first prime minister of Uganda when the country gained independence in 1962. He later served as Uganda’s president from 1966 to 1971 and 1980 to 1985. Obote was born in the village of Akokoro in northern Uganda, and received his education in his home district of Lango, at Gulu High School in Busoga, and at Makerere University College in Kampala. Over time, Obote developed into an astute and progressive Ugandan nationalist. Overthrown by Idi Amin (1924–1981) in a military coup in January 1971, Obote went into exile for eight years in Tanzania. But he returned to Uganda in 1980 and was elected for a second term as president, only to be overthrown in yet another coup staged by Ugandan military officers Tito Okello (1914–1996) and Bazilio Okello (1929–1990) in July 1985. Obote again went into exile, this time in Zambia, where he died in October 2005 at the age of eighty.

Obote's demise brought to an end a long, colorful, and controversial political career spanning nearly half a century.

During his first term as Uganda's leader, Obote supported domestic nation-building, a concept he understood to include a quickened pace of progress toward national unity in the face of Uganda’s deep social cleavages. Obote also called for economic and social transformation to uproot what he saw as the evil trinity of poverty, ignorance, and disease. On the international scene, Obote stood for East African cooperation, Pan-Africanism, and Uganda's active participation in world affairs.

Obote managed Uganda's external relations successfully, with the exception of a falling out with the United Kingdom in 1971 over Britain's sale of military arms to apartheid-era South Africa. During Obote's tenure, Uganda became not only a respected, albeit small, member of the community of nations, but the country also benefited from its membership in numerous international institutions and the acquisition of new trade and development partners. But in the domestic sphere, Obote's performance was mixed. He began well, with a remarkable record of achievements in education, health, agriculture, and the building of infrastructure. In general, government was managed on a pluralist or multiparty basis, with keen constitutional oversight, as evidenced by the numerous challenges to government actions that were presented to the courts.

The situation began to deteriorate with Obote's handling of the so-called Lost Counties of Bunyoro, a part of Uganda that Britain had handed over to the kingdom of Buganda at the beginning of its period of colonial rule. Following a referendum, Obote returned these regions to Bunyoro, despite stiff opposition from Edward Mutesa (1924–1969), Uganda's ceremonial head of state and the kabaka of Buganda. After a furious confrontation that culminated in the Battle of Mengo in May 1966, Mutesa fled into exile in the United Kingdom. Triumphant, Obote moved forward with a radical overhaul of the country's political system. He abolished monarchism and federalism under his new republican constitution of 1967. Shortly thereafter, he declared what has been called his “move to the Left” by introducing socialist principles and work methods to guide the country's development. Finally, he declared that his party, the Uganda People's Congress (UPC), was the only legitimate party. In the course of this overhaul, however, Obote failed to give adequate attention to the army, and in the end it was his military commanders, first Idi Amin and later Tito Okello and Bazilio Okello, who boosted him from power.

In his second term as president, Obote was an older and more mellowed politician, made perhaps wiser by the trials and vicissitudes of life in exile. He left behind the political excesses of his first term, including his commitment to socialism and to a one-party system, and he accepted the aid of the World Bank and the International Monetary Fund toward the recovery of Uganda's economy, which was left shattered after the reign of Idi Amin. By the time the two Okello generals staged yet another military coup, positive results had begun to be registered. Nevertheless, during Obote's second administration, the country's sharp social cleavages, particularly between the Bantu and Nilotic ethnicities and north/south regionalism, became politically relevant, and led to civil war.

Obote's management of this conflict has been a major blot on his record, not just for his inability to resolve it quickly but because of the large number of civilian deaths and the human rights abuses that occurred. Rendered helpless as an exile in Zambia, the blame for all of these issues was laid at his feet by his chief antagonist during the conflict, Yoweri Museveni, who became president of Uganda in 1986. Obote died just as he was shaping his response to these accusations. Obote is survived by his political party, the UPC, and a large body of supporters in Uganda and elsewhere, who will, no doubt, contribute to a more profound appreciation or critique of his long political career.

OBSCENITY

Throughout history, people have represented sexuality in literature and art. However, pornography, in the early twenty-first century use of the term, did not emerge as a mass industry until the late 1950s. It eventually broke into mainstream distribution outlets and had grown to a business estimated at $12 billion a year in the United States by the end of the twentieth century, with increasing acceptance in U.S. culture. While still proscribed by law in a variety of ways and considered unacceptable in many circles, pornography is used more openly, while at the same time pop culture has adopted many of the conventions of pornography.

State and federal laws in the United States uses the term obscenity, rather than pornography, to describe sexual material that can be regulated. Obscenity prosecutions in the United States were infrequent and uncontroversial in the eighteenth century and early nineteenth century. After the Civil War, obscenity became a more public issue, largely due to the work of Anthony Comstock and other conservative religious crusaders. Obscenity became increasingly politicized in the United States in the twentieth century, particularly when literary works such as James Joyce’s *Ulysses* (1922) were kept out of the country.

In 1957 in *Roth v. United States*, the Supreme Court first stated clearly that obscenity was outside the protection of the First Amendment, kicking off a string of cases in which the Court wrestled with how to define and regulate obscenity. In the 1973 *Miller v. California* decision, the Supreme Court established a three-part test for identifying obscenity, defining it as: (1) material that appeals to the prurient interest; (2) material that portrays sexual conduct in a patently offensive way; and (3) material that does not have serious literary, artistic, political, or scientific value. Further the Court identified contemporary community standards as the measure of evaluation. In decisions since *Miller*, the Supreme Court has upheld the constitutionality of zoning ordinances that restrict adult theaters and the use of racketeering statutes against businesses that sell obscene materials.

A separate category is child pornography, which comprises material that is either made using children or, in the digital age, made through the use of technology that makes it appear that the sexual activity portrayed involves children. The former is illegal (under *New York v. Ferber*, 1982); the status of the latter remains uncertain (see *Ashcroft v. Free Speech Coalition* [2002], in which the Court ruled that the section of the Child Pornography Prevention Act of 1996 that banned “virtual” child pornography was unconstitutional, calling it too broad in its scope).

*Indecency*, a term from radio and television broadcasting, defines a broader category that can be regulated. Indecent material is defined as language or material that, in context, depicts or describes sexual or excretory organs or activities in terms patently offensive as measured by contemporary community standards for the broadcast medium. The Federal Communications Commission administers indecency regulations.

Obscenity laws tend to be enforced in places where there is political support from citizens. This prosecutorial discretion means that material for sale openly in one jurisdiction may not be available in another. However, the availability of mail-order and computer pornography means that graphic, sexually explicit material can now be obtained easily anywhere in the United States. As the enforcement of legal prohibitions has lessened, a formerly underground industry with ties to organized crime has become a routine business with its own trade magazine, *Adult Video News*.

The term used most often in the public debate over sexually explicit material is pornography. This term is not rooted in law and has no commonly accepted definition. It is sometimes used as a generic term for commercially produced, sexually explicit books, magazines, movies, and Internet sites, with a distinction commonly made between soft-core material (nudity with limited sexual activity that does not include penetration) and hard-core material (graphic images of actual, not simulated, sexual activity including penetration). In other contexts the term is juxtaposed to erotica, defined as material that depicts sexual behavior with mutuality and respect. Pornography, in contrast, is material depicting sex involving domination.
or degradation. In laboratory studies of pornography’s effects, three categories of pornography have been created: overtly violent, nonviolent but degrading, and sexually explicit but neither violent nor degrading.

Up until the 1970s, debates over pornography pitted liberal advocates of sexual freedom against conservative proponents of traditional sexual morality. That dynamic changed with the feminist critique of pornography, which emerged out of the larger struggle against sexual violence during the second wave of the women’s movement in the 1960s. Feminist critics argued that discussions of the issue should focus not on questions of subjective sexual mores but on the harm to women. Pornography, they claimed, harmed all women, not just those used in pornographic material.

**OBSERVATION, PARTICIPANT**

Participant observation was introduced into anthropology at the beginning of the twentieth century when Bronislaw Malinowski (1884–1942) challenged the traditional paradigm of researchers conducting their studies from the veranda of a missionary station, by taking accounts from individuals rather than observing situations firsthand (Wax and Cassell 1979). He exhorted his colleagues to conduct fieldwork in situ, using participant observation. This technique was used by Malinowski in his studies of the Trobriand Islands (Malinowski 1922, 1935, 1948) “to grasp the native’s point of view, his relation to life, to realize his vision of his world” (Malinowski 1922, p. 25, emphasis in original). Participant observation involved a field trip of one or two years, working in the native language as a member of the community being studied. Yet Malinowski’s diary illustrates the difficulties in living up to his own demands as he had identified the ideal conditions in which to conduct participant observation, while many problems needed to be resolved in the field (Malinowski 1967).

This observational approach was taken up by many anthropologists in classic studies including E. E. Evans-Pritchard (1902–1973) on the Nuer (1940) and Margaret Mead (1901–1978) in New Guinea (1977). Since the 1960s, anthropologists have “come home” to research their own societies using participant observation to examine urban settings. Harry Wolcott (1973, 1982) studying elementary schools perceived the principal as if he were the chief of a small tribe. Sociologists have taken a similar approach, studying schools (Ball 1981; Burgess 1983), factories (Pollert 1981; Beynon 1973), hospitals (Roth 1963), and new religious movements (Barker 1984, 1987; Zablocki 2001). In sociology, the work of Robert E. Park (1864–1944) and the Chicago school (Park 1952) used observational methods to study homeless men, street-corner gangs, and delinquents. Like the social anthropologists, the Chicago sociologists were strangers in their own society; they were involved but also detached. An observational approach was also used in community and locality studies in the United States and in Britain (Lynd and Lynd 1929, 1937; Warner and Lunt 1941, 1942; Warner 1959; Frankenberg 1957; Stacey 1960; Kluckhohn 1940).

The hallmarks of participant observation involve the researcher living in the community being studied, participating with individuals, observing and talking with them and interpreting the situations observed. The researcher is the main instrument of data collection, and shares in the lives and activities of those being studied by learning their language and interpreting their behavior (Becker 1958). Participant observation involves examining social behavior as it occurs rather than as it is reported through interviews and questionnaires.

Much has been written on the roles used by the participant observer (Adams and Preiss 1960; Bryman and Burgess 1999; Gans 1999). Participant observation can be formal or informal, concealed or revealed, and can involve complete participation and complete observation. These ideal types have been extended by R. Gold (1958) and Buford Junker (1960) into four major roles: (1) the complete participant, (2) the participant as observer, (3) the observer as participant, and (4) the complete observer.

The complete participant rarely reveals that research is being conducted because the researcher does not wish to influence the conduct of the activities being studied (Festinger et al. 1956; Humphreys 1970; Homan 1978). However, in these circumstances it is difficult for the participant observer to pose questions. This puts the researcher in the role of spy and makes it impossible to distinguish everyday roles from research roles. There is also a danger of “going native” by failing to question the
activities observed (Murray 2003). Because this role infringes the principle of “informed consent,” it is rarely used. The participant as observer role involves researcher and researched being aware that their relationship stems from research activity (Roy 1970). The researcher is involved in the social situation but also detached (Cohen 2000). This role is most frequently used. The observer as participant consists of the observer making the research purpose clear from the start of the investigation, but there is no intense relationship with those researched (Schatzman and Strauss 1973; Hong and Duff 2002). Finally, the complete observer role entirely removes the researcher from any form of participation so that the purposes of the research are not revealed. All four roles are used interchangeably and can assist or impede data collection.

The role of the participant observer is influenced by his or her membership characteristics (Delaney 1988). Age and gender will influence access to groups (Whyte 1955; Patrick 1973). Gender, ethnicity, and social class will also influence the perspective from which data are collected and in some instances access will be granted to, or withheld from, certain individuals in a social setting (Golde 1970; Wax 1979; Roberts 1981; Easterday et al. 1977; Liebow 1967; Bell 1999). Participant observation also involves selection (Arcury and Quandt 1999). Many participant observers use informants in their studies to take them into social situations, explain the context in which observations occur, and provide a perspective on the social world (Casagrande 1960; Gallmeier 1988). Participant observers need to consider how informants are selected as they influence data collection (Cohen 2000).

Participant observers record data and keep detailed field notes (Lofland 1971, 1974; Schatzman and Strauss 1973; Burgess 1982, 1984). Substantive field notes provide a record of the observations, conversations, and interviews that take place (Humphreys 1970). Methodological field notes illustrate the research process and record the personal impressions of the researcher (Geer 1964; Murray 2003), the impact of roles upon data, the selection of informants and relationships with them, and an analysis of research experience. Analytic field notes record concept development throughout an investigation and contribute to data analysis and the written narrative that constitutes the article or monograph produced (Glaser and Strauss 1967; Glaser 1978; Atkinson 1990; Ashworth 1995).

Several problems have been identified when conducting participant observation. Researchers must always remember that they are located in a social setting for the purposes of social science. They are involved and yet detached. This will help them to overcome the risks of overidentifying with other participants and “going native” in the setting by no longer questioning the actions and activities that are observed. The researcher needs to collect data that are reliable and valid (Shaffir and Stebbins 1991). Ethical problems are also frequently raised for the researcher through being placed in a marginal role with the result that stress and anxiety have to be managed throughout a study. This is frequently the case in covert studies where the researcher is unable to take notes or to use a range of other methods of research and often violates principles of informed consent, privacy, and confidentiality (Burgess 1989; Lauder 2003). The participant observer therefore needs to manage the study by being aware of the problems encountered in the research process by engaging in critical self-reflection of the research experience (Bourdieu 2003) and by bringing the study to a successful close.

OBSESSION

The term obsession is used quite liberally in current popular vernacular to indicate an intense interest in or preoccupation with a subject. Despite the prevalence of this connotation, psychologists generally use the term to indicate a more severe disturbance in cognition. As defined by the American Psychological Association's Diagnostic and Statistical Manual of Mental Disorders, obsessions are “recurrent and persistent thoughts, impulses, or images that are experienced … as intrusive and inappropriate and that cause marked anxiety or distress” (2004, p. 457). This definition indicates that obsessions are identified in part by their effect on the thoughts and feelings of afflicted individuals. That is, obsessions are cognitive in content and result in negative emotions. Furthermore, obsessions are involuntary in nature and may intrude into one’s consciousness unexpectedly. Therefore, true obsessions exert a measure of control over the individual that nonpathological obsessive thoughts do not. Obsessions can have a profound impact on one’s ability to form and nurture interpersonal relationships and can lead to conflict with friends, coworkers, and family.

Delineations between normative behavior and abnormal obsessions can be somewhat difficult to ascertain. Showing an enthusiastic interest in a particular activity, topic, or person need not reflect psychopathology. Likewise, persistent worries about realistic problems do not qualify as obsessions. However, when such a thought occurs at a very high rate and is associated with significant distress to oneself or others, it is more likely to be considered an obsession. Differentiating obsessions from normative behavior also requires that one consider the developmental stage of the individual. For example, although it is not uncommon for young children to develop intense preoccupations with or fears of specific objects or interests, such behavior would be more worrisome in older individuals. Landmark studies by researchers in the 1970s and 1980s demonstrated that many people experience intrusive thoughts in the absence of any psychological impairment (e.g., Rachman and de Silva 1978). Therefore, the presence of unwanted thoughts alone neither qualifies as obsession nor confers a risk factor for mental disorder. Furthermore, marked emotional distress must accompany the thoughts in order for them to be considered obsessions. These emotional reactions can range, though many people report feeling anxious when confronted with obsessive thoughts.

Among the psychiatric disorders most relevant to obsessions are obsessive-compulsive disorder (OCD), body dysmorphic disorder (BDD), eating disorders, and delusional disorder. Individuals with obsessive-compulsive disorder usually have both obsessions and behavioral symptoms called compulsions, though an obsession-only subtype exists as well. Compulsions are ritualistic actions performed to neutralize the anxiety and distress created by obsessions. For example, a patient with obsessions about contamination may exhibit compulsive hand washing, and a patient with obsessions about harm may exhibit compulsive checking behavior. Individuals with body dysmorphic disorder have persistent unwanted thoughts about a perceived defect in their physical appearance. Common obsessions include concerns about parts of one’s body being misshapen, abnormally sized, or otherwise unattractive. Like obsessive-compulsive individuals, people with BDD also exhibit compulsions, such as repetitive grooming behavior. Researchers have linked obsessions to psychotic disorders such as schizophrenia and delusional disorder. A key feature of such disorders is that the afflicted individual suffers a severe impairment of his or her ability to experience rational thoughts and perceptions. If these irrational thoughts become intrusive and persistent, then one can be said to be experiencing obsessions. Eating disorders have been associated with obsessions, in that afflicted individuals often have persistent uncontrollable thoughts about food, dieting, body image, and exercise.

Obsessions can also affect one’s propensity to pursue and maintain social relationships via maladaptive means, such as stalking. Stalking is defined as the deliberate following and harassing of others, and victims are most commonly former intimate partners or celebrities. Although many individuals experience a desire to maintain contact following the dissolution of an intimate relationship, those who do so by threatening means or who act on uncontrollable thoughts about the loved one may meet criteria for stalking behavior.

The treatment of obsessions differs based upon the specific disorder in which the obsessions are couched.
Psychotherapeutic techniques are often augmented by medication, as in the case of OCD and BDD, or may serve as a primary means of treatment, as in psychotic disorders. For individuals with OCD, cognitive-behavioral therapy has proven to be more effective than other forms of talk therapy. The primary technique used in this therapy as it pertains to OCD is called exposure and response prevention. In this method, individuals are exposed to stimuli that raise anxiety and provoke obsessions. They are instructed to tolerate this anxiety and distress without performing any neutralizing compulsive behaviors. Although patients may experience a greater deal of distress at the onset of treatment, over time obsessions wane as individuals learn that they can tolerate the anxiety without performing a compulsion. Ideally, the obsessions themselves lose potency and become less impairing. This technique is also used to treat BDD in that patients are exposed to their obsessive body concerns and prevented from performing behaviors that combat anxiety. For example, one might be prevented from applying makeup, checking mirrors, or skin-picking if these are repetitive and anxiety-reducing strategies used by the patient.

Much of the research on the biology of obsessions has been conducted by examining individuals with OCD. Basal ganglia abnormalities are the most commonly reported structural correlates of the disorder. More specifically, the head of the caudate nucleus and the orbital gyrus may play a prominent role in the dysfunction. These structures are deep below the cerebral cortex and are implicated in the regulation and coordination of movement. In terms of neurotransmitter dysfunction, both the serotonin and dopamine systems have been implicated in OCD. Pharmacological treatments for obsessions include drugs that target the serotonin system and increase the amount of this neurotransmitter available in the brain. Serotonin reuptake inhibitors, such as clomipramine or fluoxetine, have been associated with both symptom reduction and improved quality of life for patients with both OCD and body dysmorphic disorder (McDonough and Kennedy 2002; Phillips 2002). About 40 to 60 percent of obsessive-compulsive patients report significant improvement from using a drug of this type. Combining these drugs with antianxiety drugs or neuroleptics may also be beneficial for patients, depending upon the initial response to serotonin reuptake inhibitors.

**OBSESSIVE-COMPULSIVE DISORDER**

Obsessive-compulsive disorder (OCD) is an anxiety disorder characterized by recurrent and intrusive obsessions and/or compulsions that are excessive or unreasonable, are time-consuming, and cause marked distress for the individual and/or significant impairment in global functioning. Obsessions are defined as recurrent and persistent thoughts, impulses, or images that are intrusive and inappropriate. Compulsions are defined as repetitive behaviors or mental acts that are performed in response to an obsession or according to rigid rules in order to prevent or reduce distress.

Common obsessions seen in individuals suffering from OCD are fear of contamination from germs, dirt, and environmental toxins; doubts about safety—having harmed the self or others; the need for symmetry, exactness, and order—having things “just right”; fear of making mistakes and acting socially inappropriate; intrusive sexual thoughts or urges; excessive religious or moral doubts—having “forbidden thoughts”; and the need to tell, ask, or confess. Common compulsions include washing and cleaning, checking, ordering and arranging, hoarding and collecting, repeating, touching, praying, counting, reassurance seeking, making mental lists, and retracing past memories.

People with OCD are sometimes overwhelmed by their disturbing obsessions, which seem uncontrollable and cause intense anxiety. To reduce the discomfort generated by the obsessions, an OCD sufferer avoids the feared situation and/or engages in compulsions repeatedly and ritualistically, which may relieve the discomfort but only temporarily. This pattern eventually develops into a vicious cycle of obsessions and a complicated web of compulsions. However, not all people with obsessions perform compulsions.

About 2 to 3 percent of Americans, as many as seven million people, have OCD at some point in their lives. OCD can happen to anyone and usually begins in adolescence or early adulthood, but the disorder can also occur...
in children. Seventy-five percent of those who develop it show symptoms by age thirty. OCD starts earlier in boys than in girls. In adults, men and women are affected in equal numbers. In some cases, OCD begins after a trauma. Cases involving the interplay of OCD and post-traumatic stress disorder (PTSD) precipitated by trauma need to be treated by addressing both disorders. OCD may co-occur with conditions such as Tourette’s syndrome, attention deficit disorder, other obsessive-compulsive spectrum disorders, and other anxiety disorders. Depression is often a secondary symptom to OCD.

Like many psychiatric disorders, OCD appears to result from a combination of biological and psychological factors. Some people may have a biological predisposition to experience anxiety. Research suggests that abnormal levels of the neurotransmitter serotonin may play a role in OCD. Brain scans of OCD sufferers have revealed abnormalities in the activity level of the orbital cortex, cingulated cortex, and caudate nucleus. OCD tends to develop when these biological factors are combined with a psychological vulnerability to anxiety. Some individuals may have learned that the world is a potentially dangerous place over which one has little control. This learned belief of danger is then overvalued and misattributed to one’s lack of control over the environment.

OCD can have disabling effects on a sufferer’s life. Individuals with severe cases of OCD may need hospitalization to treat their obsessions and compulsions. People with OCD must allow a great deal of extra time to complete seemingly routine tasks. Individuals may avoid going to certain places or engaging in certain activities due to their own embarrassment about their compulsive behavior. Furthermore, family members of individuals with OCD may feel anger, frustration, and/or guilt when the sufferer’s compulsive behaviors interfere with family functioning. OCD is a chronic illness that, like other psychiatric illnesses, has periods of exacerbation followed by periods of relative improvements, though a completely symptom-free interval is generally unusual. With appropriate treatment, most sufferers show considerable improvements.

Exposure and response prevention (ERP), a form of cognitive-behavioral therapy, is the most effective type of psychotherapy for OCD. Essentially, OCD sufferers are repeatedly exposed to those anxiety-provoking thoughts and situations that they fear, but are prevented from engaging in their compulsive rituals and avoidance behaviors. The basis for ERP allows an individual the opportunity to learn that simply tolerating the obsessions without avoidance or compulsions will gradually lead to reduction in anxiety and extinction of obsessive fears. In turn, the occurrence of obsessions is reduced, and the vicious cycle eventually dissipates. Intensive ERP alone is often effective enough for many individuals with OCD.

OCD treatment using certain medications may be beneficial, but generally is not as effective as intensive ERP. Medications considered for the treatment of OCD are usually antidepressants known as selective serotonin reuptake inhibitors (SSRIs), which are often effective without severe side effects. These SSRIs, which include fluvoxamine (Luvox), fluoxetine (Prozac), sertraline (Zoloft), and paroxetine (Paxil) increase the serotonin available in the brain. Clomipramine (Anafranil), a tricyclic antidepressant, is another Food and Drug Administration–approved OCD medication that is more effective than SSRIs but has unpleasant side effects. In more resistant cases of OCD, an SSRI and clomipramine may be combined. Finally, although psychotherapy using ERP is commonly integrated with the use of medication, this treatment combination has not been established as generally superior to intensive ERP alone.

OCCAM’S RAZOR
Oc cam’s Razor (Ockham’s Razor) is also known as the Law of Economy, the Law of Parsimony, or the Principle of Parsimony. It says “entities are not to be multiplied beyond necessity” (Entia non sunt multiplicanda praeter necessitatem). Another form of the principle is “plurality should not be posited without necessity” (Pluralitas non est ponenda sine necessitate).

The principle claims that to explain something, all competing explanations should be “shaved” away until only the simplest remains. When applied to the construc-
tion of theories explaining a phenomenon in the event that competing hypotheses provide contradictory explanations, the one that uses the least theoretical assumptions is probably the more accurate. If a detective is reconstructing the facts of a murder, the “theory” of the crime will be the one that best fits the facts and is usually the simplest hypothesis. This principle agrees with the philosophy of science’s understanding that nature’s character is simple.

The idea of parsimonious simplicity is found in limited form in the works of Aristotle. It was championed by William of Ockham (c. 1280–1349), after whom the term “Occam’s Razor” was named. It was also used by Galileo Galilei (1564–1642) when discussing the data describing the orbits of the planets in support of the Copernican model.

Opponents of Occam’s razor proposed anti-razors which say where fewer entities do not suffice, posit more. For example, in biblical textual analysis, if a scholar is faced with variant readings from different manuscripts the problem is which variant is the one closest to the original autograph of the biblical writer? The general rule, in the absence of evidence to the contrary, is to choose the more complicated reading. The reason is that a few scribes and others who copied and transmitted the thousands of surviving manuscripts sometimes tried to “correct” an apparently unclear, complicated reading by “simplifying” it.

Occam’s razor is used in philosophy, learning theory, econometrics, public policy choices and other disciplines. In public policy choices the principle is used by analysts to show that self-interest motivates voters and that the desire for reelection motives legislators, both of which are the simplest explanations for voter and legislator behavior.

Econometrics uses Occam’s razor in labor economics, financial operations studies, resource allocations, and other areas as an aided method for discovery, problem solving, or learning. It is applied as the principle that what works well and is simple will probably work best in decisions concerning poverty funding for the developing world.

Currently Occam’s razor is a characteristic of alife (artificial life) studies of ecological systems. Alife uses computers, simulations and other techniques in an information systems “bottom up” approach to study the ecology associated with living organisms and how they interact with their environment.

Some anti-razorists reject Occam’s razor as inadequate to explain complicated phenomena. The facts of experience tell them that a complicated model may require a complicated explanation, while at other times simplicity is the most effective.

**OCCULT, THE**

Properly speaking, the occult refers to a body of traditions concerning religious practices preserved and practiced outside of organized religions. It includes alternative means of inducing religious ecstasy, contacting supernatural beings, healing, and foretelling the future. The word itself derives from a Latin term occultus, meaning something “covered over” or hidden from ordinary view. In this sense, it has long been used in the sciences—for example, to refer to symptoms not easy to detect, as in occult carcinoma. In the 1500s the term was first extended to abstract ideas that were difficult for the uneducated mind to grasp. By the mid-1600s, it had come to refer to esoteric practices, such as alchemy and astrology (the occult philosophies). The term occult soon came to imply a body of knowledge, including mastery of magical rituals, passed down in secret by a select group of masters.

In modern usage, the term is often linked to or even confused with the term cult, which is (as popularly understood) a group that practices a potentially dangerous religion. However, the terms are not etymologically related: cult is derived from the Latin verb colere, meaning to plant and care for crops (whence the related terms cultivate and culture). Nevertheless, even in ancient times occult religions were often defined as dangers to the state, and their followers liable to persecution.

For instance, when the Bacchanalia, a Greek mystery religion, was introduced into Italy in the second century BCE, the Roman Senate responded with an investigation. According to Livy’s *History of Rome* (Book 39), they learned that its agenda was to entice large numbers of adolescents from noble families to engage in “secret and nocturnal rites” of promiscuous sex and debauchery, then use them to overthrow the state. Its secrecy was maintained, supposedly, by murdering those members whose loyalty was suspected, in some cases so discreetly that “not even
the bodies could be found for burial.” Similarly, in the second century CE, the early Christian church was persecuted because it was suspected of holding ritual sex orgies and baby sacrifices, motifs that have remained part of contemporary legends about “the occult” to this day.

In the seventeenth century, the rise of fraternal organizations such as the Rosicrucians and Freemasonry led to a widespread interest in esoteric mystical traditions among intellectuals. A series of pamphlets published in German from 1614 to 1616 described the “Rosicrucian Fraternity” as an occult organization, founded by one Christian Rosencreutz, who had allegedly obtained mysteries of nature and the gift of curing diseases from Arabian magi. The original pamphlets may have been a hoax; nevertheless, from this point on many groups emerged, offering mystical knowledge and access to superhuman powers to those willing to undergo initiation. The British historian Frances A. Yates (1899–1981) located a reference to such a group in a Scottish poem dated 1638:

For what we do presage is not in grosse,
For we be brethern of the Rosie Crosse;
We have the Mason Word and second sight
Things for to come we can foretell aight.

(Yates 1972, p. 211)

This is the earliest known reference to the fraternal organization of Freemasonry, which claims to maintain occult knowledge about the nature of God and the universe, deriving from the architects of Solomon’s Temple in biblical times. Certainly one of its early claims was the ability to give “second sight,” or the gift of divining the future. In any case, the Masonic movement that developed during the next century cautioned its initiates to keep its secrets with a solemn oath, inspiring many modern practitioners about their true practices.

Such fraternal secret societies inspired many social panics from the 1600s onward, but they also influenced the revival of esoteric magic in the nineteenth century. Spiritualism, originally based on rural folk practices of divination, became a popular phenomenon among intellectuals in the mid-nineteenth century. This practice, along with the rituals of Masonry, influenced the turn-of-the-century Order of the Golden Dawn. This group, a loose association of academics and seekers in Great Britain, attempted to reconstruct the practices of earlier ceremonial magicians from scattered historical records and details of Masonic and Rosicrucian rituals. The Golden Dawn participants, who included A. E. Waite (1857–1942), the Irish poet William Butler Yeats (1865–1939), and, for a time, Aleister Crowley (1875–1947), published widely on their occult theories.

A generation later, Gerald Gardner (1884–1964) and a circle of friends created a system of rituals based on these speculations that led to the neo-pagan revival, one of the most rapidly growing new religions in the Anglo-American world. A growing body of self-help books published by modern pagans has reintroduced a general public to practices based on these and other occult traditions.

Those aligned with traditional religion have always been antagonistic to such practices, seeing them as spiritually dangerous or even satanic in nature. Naive contact with such powers, many fundamentalist Christian authors warn, could expose practitioners to demonic influence, and could even make them susceptible to cult leaders. However, there is little evidence that the rituals taught by occult movements are, in fact, much different from similar ones preserved in folklore or by non-Western religions. Anthropologist Sabina Magliocco, herself an initiate into a neo-pagan religion, has argued that the occult is a powerful, affirming means of reclaiming “traditional ways of knowing that privilege the imagination” (2004, p. 97). Occult ritual allows the participants to generate and control extraordinary experiences, she concludes.

The occult can best be characterized as a tendency within religious expression that values individual spiritual experience over theology or self-discipline. Often based on a nativistic perspective, it expresses a longing to rediscover an imaginative realm with which contemporary religion has lost touch. The result permits the worshiper to participate directly in the mythological world. Occult practices appeal to those who are bored by the tendency of mainstream religions to channel religious power vicariously through trained specialists. Paradoxically, religions often revive themselves by incorporating elements of the occult into their own practice. In fact, many contemporary charismatic factions within Christianity promote an experience-centered faith that contains elements of divination, spirit possession, and magical healing similar to those taught within occult movements.

OCCUPATIONAL HAZARDS

Dictionaries as well as legislation generally define occupational hazards in terms of risks that are inherent in certain types of employment or workplaces such as deep-sea diving, cutting timber, mining, high-rise steel construction, high-voltage electrical wiring, using pesticides, and painting bridges. From the perspective of the social sciences, however, occupational hazards are less an issue of inherent dangers in certain types of work than an issue of the dangers that arise from (1) structural conditions, in particular power imbalances between employees and bosses (2) poor working conditions, such as double shifts or overcrowding (3) inappropriate demands made on unsuitable employees, such as children (4) insufficient monitoring of workplace safety.

Work-related risks and illnesses throughout time have been shaped by the forces that shape the nature of work itself. Changing modes of production, shifting economic powers, and demographic changes in the workforce all impact who is injured at work, how and why the injury occurred, and to what extent—if at all—the injury is recognized and acknowledged.

Considering that almost all humans work either inside or outside the home for most of their lives, the field of occupational health has received relatively little attention from the medical profession. Occupational physician Michael Gochfeld notes that medical writers as early as Hippocrates (c. 460–c. 370 BCE) and Galen (c. 129–216 CE) sporadically acknowledged links between health problems and specific occupations (typically mining). The emerging public health movement in the mid-nineteenth century addressed the overall unhealthy living and working conditions of immigrants and slum dwellers. It was only with the rise of labor unions in the early twentieth century that significant legislative and medical notice has been given to occupational hazards.

Throughout the twentieth and into the twenty-first centuries, definitions of, responses to, and compensation for occupational injuries continue to be highly contentious. In the United States, for example, the Occupational Safety and Health Administration (OSHA), the federal agency charged with enforcing safety and health legislation, is considered by many to be underfunded and understaffed (employing less than 2,200 inspectors for over 7 million workplaces). According to industrial hygienist Lisa Cullen, OSHA is as likely to protect the “corporations responsible for maiming and sickening workers” as it is to protect the workers themselves.

In the United States, foreign-born workers increased 22 percent from 1996 to 2000, while fatal injuries among foreign-born workers increased by 43 percent, according to a 2004 analysis published in Monthly Labor Review. Oftentimes, the injuries sustained by foreign-born workers are not reported by employers who wish to avoid paying workers compensation benefits. Injuries may also not be reported by workers who are unaware of American policies concerning injuries on the job or fear deportation in the case that they are undocumented. Vernon Mogensen (2005) shows that pursuant to free-market globalization, “The outsourcing of jobs from high-wage to low-wage locales has the effect of transferring relatively safe jobs from developed countries, where safety standards and trade unions are well-established, to more dangerous locales like China, where bonded-, prison-, and child labor is abundant, but both safety and health enforcement and free-trade unions are virtually nonexistent.”

As economies have shifted from industrial to post-industrial and from local to global, public and legislative notions of occupational hazards have not kept pace. A popular tendency to focus on dramatic occupational hazards such as coal mining or sky-scraper construction may obfuscate the many occupational settings that are permeated by illness-inducing substances (e.g., chemical pollutants) or job tasks that demand repetitive motions that can cause injury over time. The perils involved in long days spent looking at computer monitors and typing are not the stuff of cinema heroics, but they have become among the most common hazards of the post-industrial workplace. Injuries and illnesses resulting from work in the rapidly expanding service sector are good examples of occupational hazards that rarely merit financial compensation. Nurses’ aids often suffer back injuries as a cumulative result of lifting patients, telemarketers experience stress and depression from the steady stream of insults from people they are assigned to call, and the growth of all-night businesses means that more workers are exposed to the hazards of disrupted sleep cycles. For the most part, these conditions are not recognized either via workers’ compensation legislation or in the public eye as “official” occupational hazards.

The definition of what constitutes a “workplace” is far from uncontested. Anthropologist and historian Harriet Rosenberg argues that all three aspects of women’s domestic labor—housework, motherwork, and wife-work—contain potential risks ranging from heavy lifting to lack of sleep and marital rape, yet illness and injury aris-
ing from domestic labor are rarely compensated for or even recognized as injuries on the job.

**OCCUPATIONAL REGULATION**

Occupational regulation refers to state approved standards for either being listed as qualified or being licensed to perform certain tasks or jobs prescribed by the government. Standard forms of occupational regulation include licensure, certification, and regulation.

The most restrictive form of occupational regulation is * licensure*. The nonprofit Council on Licensure, Enforcement and Regulation (CLEAR), which is affiliated with the Council of State Governments, refers to licensing as the “right-to-practice,” and under such laws it is illegal for a person to practice a profession without first meeting state standards (Brinegar and Schmitt 1992). Licensing standards usually involve detailed educational requirements, statements of good moral character, and a test.

A less restrictive form of occupational regulation is *certification*, in which states grant title (occupational “right-to-title”) protection to persons meeting predetermined standards. Those without certification may perform the duties of the occupation, but may not use the title.

The least restrictive form of occupational regulation is *registration*. This form of regulation usually requires individuals to file their names, addresses, and qualifications with a government agency before practicing a specified occupation. The requirements may include posting a bond or filing a fee. The regulation of occupations in the United States and other nations falls under this continuum of less restrictive to highly restrictive forms of government regulation.

In the United States, occupational licensing is a fast-growing form of regulation. During the early 1950s, about 5 percent of the labor force was covered by licensing laws at the state level. By the 1960s, the number of persons working in licensed occupations had grown to more than 10 percent of the U.S. workforce, with an even larger number if city and county licenses for occupations are included. The number and percentage of licensed occupations has continued to grow, and data from the Occupation and Employment Survey and the 2000 Census show that approximately 20 percent of the workforce in 2000 was employed in occupations licensed by states (Kleiner 2006).

In 2003 the Council of State Governments estimated that more than 800 occupations were licensed in at least one state, and more than 1,100 occupations were either licensed, certified, or registered. However, only about fifty occupations were licensed in all states. Universally licensed occupations range from doctors, dentists, lawyers, and teachers to barbers and cosmetologists. Occupations that are licensed in some states but not in others include loan officers, respiratory therapists, and electricians. However, cities and counties represent a fast-growing venue for occupational regulation. Local governments regulate many of the construction trades, such as plumbers and electricians, even though state or federal statutes often do not regulate them. There is large variation among the states in licensing occupations. For example, California licenses almost 180 occupations, whereas Kansas licenses few than fifty. There are similar variations in the percentage of the occupational workforce that is regulated.

During much of the nineteenth century, few U.S. states required government permission for individuals to work in an occupation. With urbanization and the increasing complexity of tasks, however, occupational affiliation became the dominant association for many workers. Evidence from the academic literature suggests that the quality of services improved when lower-quality purveyors were excluded. Demand for services grew as consumers perceived the regulated services to be of higher quality. Over time, as members of the occupation came to dominate many of the licensing boards, entry requirements tightened and mobility between states and coun-
tries was restricted. Prices for licensed services increased and earnings for practitioners became higher than for comparable occupations with similar levels of human capital investment and experience. For consumers who could afford licensed services, quality rose. One of the major controversies in the area of occupational regulation is whether such regulations in fact raise quality or simply restrict competition.

In most cases, the available empirical evidence shows that licensing causes a rise in prices, but its impact on the quality of services rendered is unclear (Cox and Foster 1990). For practitioners of the service, licensing leads to a rise in wages. For example, switching to a licensed occupation from an unregulated occupation raises wages 17 percent in comparison to switching to an unregulated occupation from a regulated one. On average, working in a regulated occupation raises the wage premium approximately 10 to 12 percent relative to similar unregulated occupations. This value is at the lower end of the range of the union wage impact in the United States. Working in the same occupation in a state that requires licensing raises wages 4 percent relative to an unregulated state. Statistical estimates of the costs of licensing show that this form of occupational regulation reduces output in the United States by less than one-tenth of 1 percent of total consumption expenditures annually. Some argue that this is a small price for the potentially enhanced quality that is generated by occupational regulation.

Regulation of occupations in the European Union focuses on restrictions following entry into an occupation to a greater extent than occurs in the United States (Garoupa 2004). In the European Union, occupational regulations generally limit prices and regulate the structure of organizations of licensed workers. Most occupational entry restrictions also regulate the number of individuals who are admitted to schools that train workers for the regulated specialty. The results from statistical estimates show that licensing has a smaller impact on earnings in the European Union than in the United States. Unlike the United States, nations such as Germany are deregulating many of their previously licensed occupations, suggesting that the practice of occupational regulation can be reversed in response to public pressure.

**BIBLIOGRAPHY**

**OCCUPATIONAL SAFETY**

Highly publicized job accidents, such as mining disasters, create the impression that occupational safety is a haphazard enterprise. Although accidents are random events, occupational safety levels are governed by a variety of social institutions and display systematic patterns across time and across different types of industry. Thus, the probability of occupational injuries and illnesses varies in a quite predictable manner even though the occurrence of particular accidents usually cannot be foreseen.

From the standpoint of economic analysis, firms provide specific safety levels by striking a balance between the costs to the firm of accidents and the costs of providing greater safety. The differences across industries in the costs of providing safety account for the higher risk levels of industries such as mining and construction, where eliminating risks is very costly, as compared to safer industries such as banking. Firms will incur these costs to promote safety if they have a financial incentive to do so. The chief sources of the financial incentives that lead firms to provide a safe workplace are wage premiums that they pay to workers on risky jobs, workers’ compensation costs, and government health and safety regulations.

The economic analysis of occupational safety dates back to Adam Smith. Workers require higher pay, or compensating differentials, to be attracted to dangerous jobs. This wage premium usually is not in the form of hazard pay but rather is part of the higher overall pay package required to attract workers to risky jobs. In the United States, these wage premiums totaled $229 billion in 2000, or about 5 percent of all worker wages. Studies have documented similar but lower wage premiums throughout the world in countries ranging from India and Taiwan to the United Kingdom.

A useful shorthand puts these wage premiums in perspective: Suppose that the average worker faces an annual occupational fatality risk of 1 in 20,000 and receives about $350 for facing that risk. Put somewhat differently, if there were 20,000 workers facing a comparable risk, there would be one expected death in the group and $7
million paid in wage compensation for risk. Thus, the total wage compensation per expected death is $7 million, which economists often refer to as the value of statistical life (VSL). This $7 million figure is the average VSL estimate based on U.S. studies.

Estimates of the VSL only pertain to the tradeoffs workers make between very small job risks and the wages they require to accept these risks. They do not imply that a worker would be willing to accept certain death for a payment of $7 million, or that a worker would have the resources to pay that amount to avoid the certainty of a job-related death.

Although the incentives that wage premiums for risk provide are often substantial, market forces may not be adequate. Market incentives will fall short if inadequate knowledge of health and safety risks impedes worker decisions. Market incentives also do not capture society’s broad altruistic concerns with worker health. Finally, wage premiums alone do not address the insurance needs of injured workers.

As a result, several modes of government intervention have been developed to address these shortcomings. Since the early twentieth century, states have instituted workers’ compensation plans that compensate workers for accidents irrespective of where fault lies. The workers’ compensation premiums that firms pay totaled $32.9 billion in 2003. These costs create powerful incentives for safety, as firms with better safety records pay lower insurance premiums. This linkage of premiums to accident-prevention performance is particularly strong for large firms. Statistical estimates indicate that worker fatality rates would be one-third higher than they are now in the absence of these safety incentives.

Beginning with the passage of the Occupational Safety and Health Act of 1970, there has been direct federal regulation of workplace safety in the United States. These regulations have largely taken the form of standards that either specify safe workplace technologies or set maximum limits on exposures to dangerous chemicals. In addition, there are also important informational requirements, such as standards governing the proper communication of hazards associated with various chemicals. Firms are subject to inspection to ascertain if they are meeting regulatory standards, and those firms out of compliance incur fines. The magnitude of these financial penalties has been modest but rising over time, with total fines in fiscal year 2002 equaling $149 million. Most published studies indicate an effect on occupational injury rates on the order of a 2 to 4 percent reduction in the frequency of job injuries, but the increase in penalty levels since the 1990s may generate greater effects on safety.

The net effect of these different societal mechanisms to reduce risk has been a tremendous improvement in occupational safety. The workplace fatality rate has declined steadily over the past century. The workplace fatality risk was ten times greater in 1928 than in 2003, and the 2003 figure represents a 25 percent decline over the preceding decade, though some of that improvement may be due to changes in data reporting practices.

Two contributors to this long-term improvement in safety are noteworthy. First, the rise in societal wealth has increased the value workers and society more generally place on risk reduction. This increased wealth boosts the wage premiums firms must pay to attract workers to risky jobs, thus leading firms to introduce safer workplace conditions to reduce these costs. Greater societal wealth also increases public support for government regulation, which tends to be less pronounced in less advanced economies. Second, technological improvements over time have led to the production of safer technologies and improvements in safety equipment. Consequently, the costs of promoting safety have also declined so that firms can strike a balance between the costs of safety improvements and the costs of a risky workplace that leads to lower risk levels.

These differences in wealth and technologies also contribute to differences in safety levels across countries. International differences in workplace safety levels and regulatory regimes are to be expected given differences in societal wealth. Less advanced countries also may lack access to modern, safer technologies. However, increased affluence and economic progress in these developing countries is likely to increase their safety levels over time.

**OCCUPATIONAL SCORE INDEX (OCCSCORE)**

The Occupational Score Index (OCCSCORE) is a measure of occupational reward that is available across decennial census datasets from 1850 to 2000. It was developed at the Minnesota Population Center as part of the

**Occupational Score Index (OCCSCORE)**
Occupational Segregation

Integrated Public Use Microdata Series (IPUMS). The index is based on 1950 occupational classifications. As a first step in constructing the index, occupation codes for each decennial census dataset were re-categorized into the 1950 classification structure. This yielded one, common occupational classification across all decennial censuses. The IPUMS staff then quantified this common occupational structure using median total income for each occupation as reported in a 1956 Special Report published by the Census Bureau. The values for OCCSCORE are presented in hundreds of 1950 dollars. As an example, if median total income for economists was $20,000 in 1950, OCCSCORE would equal 20 for economists in all decennial census datasets.

OCCSCORE has two major uses. First, it provides a proxy for income in decennial censuses prior to 1960 that lack individual income data. Second, it provides a consistent measure with which to compare labor market outcomes from 1850 to 2000. However, OCCSCORE has four major shortcomings. First, it does not account for changes in occupational hierarchy across time. For each decennial census dataset, OCCSCORE conveys the rank ordering of occupations by income in 1950. However, the actual rank ordering of occupations likely changes over time. Second, the index does not account for variation in income within occupations. For example, in a given decennial census year, two individuals working in the same occupation have the same OCCSCORE value. However, based on items such as tenure and education, individuals with the same occupation may have very different incomes. Third, the index does not account for cost of living differences. An individual working as an economist in San Francisco, California, has the same OCCSCORE as an economist in Omaha, Nebraska. However, their respective purchasing powers are clearly different. Finally, although the IPUMS staff has taken great care when constructing OCCSCORE, re-categorizing occupations into the 1950 classification is problematic. New occupations evolve over time, and the U.S. Census has periodically changed the occupational classification system.

The primary alternative to the OCCSCORE is a set of prestige indices. Prestige indices are typically based on regression models where income and education are used to predict responses to an occupational prestige survey. The predicted values from these models are then used to predict the prestige of an occupation. Unlike prestige indices, OCCSCORE only measures the monetary return to occupations, not status or prestige. Overall, prestige scores have been more widely used in social sciences research, because occupation augmented by information on income and education is thought to be a better indicator of socioeconomic status than just the monetary return to occupation. One disadvantage of prestige indices is uncertainty about models’ predictions of prestige.

Overall, OCCSCORE is a useful measure of occupational reward for research using censuses prior to 1960. For research focused only on 1960 or later, however, individual income measures are superior.

OCCUPATIONAL SEGREGATION

SEE Crowding Hypothesis.

OCCUPATIONAL STATUS

Occupational status is a fundamental measure of social standing that reflects the distribution of power, privilege, and prestige associated with positions in the occupational hierarchy, and is a key measure of socioeconomic status (SES). Occupational status is a popular measure of SES because it can be measured reliably in surveys, is more stable over time than economic measures of SES such as individual income, and better reflects social position over the life course than educational attainment, which typically is achieved in early adulthood (Hauser and Warren 1997). Occupations are defined in the United States by the Bureau of the Census, forming a classification of several hundred categories that is modified each decade to incorporate labor market changes. Various measures of occupational status generally are linked to these census occupation categories.

EMPIRICAL MEASURES OF OCCUPATIONAL STATUS

Key empirical measures of occupational status include occupational prestige scales and socioeconomic indices. Occupational prestige measures are generated from the rankings of occupations by survey respondents on the basis of their relative “prestige” or “social standing” and have shown high consensus among individuals from different social positions, across societal contexts, and over time (Blau and Duncan 1967; Hodge, Siegel, and Rossi...
An early occupational prestige scale was based on Cecil North and Paul Hatt's National Opinion Research Center (NORC) survey in 1947, but it covered only ninety occupational titles. In 1971, Paul Siegel constructed a prestige scale for the entire U.S. Census occupational classification in 1960, based on surveys conducted between 1963 and 1965 by Peter Rossi and Robert Hodge. An international occupational prestige scale was developed by Donald Treiman (1977) several years later. The U.S. General Social Survey (GSS) used the Siegel prestige scale until a 1989 GSS module designed by Robert Hodge, Judith Treas, and Keiko Nakao was used to construct a new prestige scale for the 1980 census occupational classification (Nakao and Treas 1994).

The Duncan Socioeconomic Index (SEI) and later iterations of the SEI are in greater use today than occupational prestige scales because they are more highly correlated with other variables of interest and better describe socioeconomic differences between occupations (Featherman, Jones, and Hauser 1975). The initial SEI was constructed by Otis Dudley Duncan by regressing the percentage of "good" or "excellent" prestige ratings for forty-five of the 1947 NORC prestige scores on age-adjusted percentages of men in the occupation who completed high school or more and who reported at least $3,500 in 1949 income. Resulting regression coefficients were used as weights to construct an SEI score for each U.S. census-defined 1950 occupation category, with scores ranging from about 2 (ship- and boat-building laborers) to 96 (dentists). Updates to the original Duncan SEI have been constructed for the 1960 (Blau and Duncan 1967), 1970 (Stevens and Featherman 1981), 1980 (Nakao and Treas 1994), and 1990 census occupation categories (Hauser and Warren 1997), and a Standard International Socioeconomic Index of Occupational Status (ISEI) has been developed (Ganzeboom, de Graaf, and Treiman 1992).

Empirical research has shown that in general, race/ethnicity is a stronger determinant of occupational status than gender. Traditional women's jobs have a lower average status than male-dominated jobs, but few women work in extremely low-prestige jobs, resulting in similar average prestige scores for men and women (Acker 1980). By contrast, while some Asian Americans meet or exceed average white SEI scores, African Americans, Hispanics, and American Indians have significantly and persistently lower occupational status (Hirschman and Snipp 1999). Nonetheless, while men and women tend to be found in occupations throughout the occupational status hierarchy, there is more segregation between the occupations done by men and women than between the occupations done by blacks and nonblacks in the United States (Treiman and Hartmann 1981).

**CRITIQUE OF OCCUPATIONAL STATUS SCALES**

The use of continuous scales of occupational status to measure social standing has been criticized by social-class theorists, who classify individuals or households on the basis of their membership in one of a small number of discrete and broad social classes. The Marxist tradition divides individuals into classes based on their ownership of productive assets in the economic sphere, while Weberian approaches also incorporate dimensions of social honor within status groups and other aspects of lived experience outside the productive sphere, rather than viewing social standing as a product of one's attained education and income. Social-class theorists from across these traditions argue that continuous occupational status scales do not capture the crucial sources of power and conflict that divide social classes (e.g., owners of factories and workers in those factories), or the sense of shared class membership that could lead to collective action (Parkin 1971; Poulantzas 1975). Modern social-class typologies such as Eric Olin Wright's (1977) neo-Marxist model are used to assess how membership in a particular social class, determined on the basis of ownership of productive assets, authority on the job, and skill and training assets, influences key social outcomes such as earnings, attitudes, and life chances. However, recent research maintains that continuous and hierarchical measures of occupational status may be better predictors of these key outcomes than broad social classes in capitalist countries such as the United States and Japan (Schooler and Schoenback 1994). A further addition to the debate are the “new class maps” created by Grusky and his colleagues (Grusky and Sorensen 1998; Weeden and Grusky 2005) that employ disaggregated occupational groupings as a measure of social position preferable to either the traditional “big social classes” or continuous occupational status scales.

OEDIPUS COMPLEX

Sophocles, one of the great Greek playwrights, is best known for his Oedipus trilogy based on the tragic myth of the king of Thebes, who unknowingly slew his own father and married his own mother. When he learns of the truth of his deed, great tragedy befalls him. Some 2,500 years later, Sigmund Freud, the father of psychoanalysis, shocked the scientific world with his then radical ways of treating mental illness through a “talking cure.” This cure was based on a theory of personality in which people were driven by sexual and aggressive desires, which were clearly evident in young children. In his early case histories of Anna O, Dora, and Little Hans, for example, he discerned a clear pattern—little children seemed to have sexual feelings toward the opposite-sexed parent and feelings of jealousy and hostility to the same-gender parent that he or she would like to replace. But these children often felt guilt over both the erotic and aggressive feelings that might prompt later neurotic symptoms. Freud framed his theory of neurosis as the “Oedipus complex,” named after the fabled story of King Oedipus. Freud would claim that all neuroses were based on this early “family romance,” which he claimed was universal.

In Freud’s theory of the stages of psychological development, in which the social intersected with the developmental, he postulated that children went through an “oral stage” of dependency and attachment to the caretaker(s) via sucking the breast, an “anal stage” of learning self-control, and an “Oedipal stage” in which the young child felt erotic desire for the opposite-sexed parent and resentment to the parent of the same sex whom he or she aspired to replace. Girls felt angry toward their mothers who denied this wish and were thought to have castrated the little girls, who then suffered “penis envy,” which today is understood more as based on male status and power than genitalia. Little boys feared that their sexual feelings to the mother would be greeted by a violent expression of paternal revenge, castration, and were left with enduring anxiety over their masculinity. In both cases, the turmoil of the Oedipus complex eventually resolved when the child identified with its parents as role models for its personality and mediators of society’s values, which were then internalized as one’s conscience—the superego. Henceforth, the child would submit to the internalized voice of authority, repress its desires, and renounce the desire for the opposite-sexed parent. Thus, for Freud, the Oedipus complex was the basis of (1) the superego ( conscience) and the guilt upon which civilization depended, (2) the foundation of gender identity, (3) later choices of a mate, and (4) the central core of neurosis.

Freud has been significant for social theory because of his concerns with the emotional side of socialization and development and the applications of his theory to important aspects of social life. In common with many Enlightenment thinkers who embraced a “social contract theory,” he saw that passions and desires needed to be restrained in order for people to live together in relative harmony. In his early story of the origins of the Oedipus complex that were evident in primitive incest taboos, he theorized that people once lived in “primal hordes” ruled by a powerful patriarch who monopolized sexual access to the women of his group, including his daughters. When the sons reached puberty, they were excluded from the...
group. But, sexually deprived and outnumbering him, they banded together, overthrew and slew the father, and ate his body to incorporate his power. But soon they felt remorse over the deed and henceforth vowed to repress their desires for the sake of joint living. In Freud’s theory of civilization, the Oedipus complex was the psychological foundation of civilization. Socially required constraint was maintained by the repression of desire through fear of punishment from within. People experienced this fear as guilt, as much about unconscious wishes as about actual conduct. Renunciation—at the cost of suffering—was the price of civilization that enabled collective adaptation.

Freud saw similar dynamics operating in religion, which he considered an illusion of an all-powerful, benevolent father who gratifies frustrated wishes and provides people with the happiness that actual fathers, and real-life circumstances, typically deny. His theory of group psychology suggested that people were likely to submit to the authority of a father figure to gain his love and recognition. Moreover, the common attachment to the same leader fostered unconscious attachments between group members.

Freud’s theories were controversial from the start. He was attacked on scientific as well as moral grounds. His theories have been difficult to test, especially by the “objective” methods typical of social sciences. One of the earliest to examine of the Oedipus complex was anthropologist Bronislaw Malinowski ([1927] 2001), who claimed that among the Trobriand Islanders, where the maternal uncle rather than the father disciplined the (male) child, Oedipal resentment was directed to him, not to the father who had sexual access to the mother. More recent studies shed doubts on Malinowski’s findings. Recent French theories such as those of Michel Foucault and Jacques Lacan have recast the theory in terms of internalized discipline mediated through language, while Gilles Deleuze and Félix Guattari suggested that the Oedipus complex is fostered by capitalism to sustain its power.

Today, the Victorian family, with the father as breadwinner and mother as sole, full-time homemaker, has practically disappeared. So, too, has the classical Oedipus complex been rethought. (See Young 2001 for a recent review of the concept.) Many families consist of single parents and children, second marriages with step-siblings, and other configurations. As with any major theoretical framework, over time psychoanalysis underwent changes in theory and practice. For example, the work of Karen Horney, Erich Fromm, and Harry Stack Sullivan stressed social life and interaction. The British “object relations” theories and the “self psychology” of the Chicago school paid more attention to earlier stages of development, with concerns about early attachments and the adequacy of early caretaking and/or the extent to which the infant’s emerging self is given empathic recognition. Thus, children need to separate from symbiotic ties with caretakers, which can overwhelm and stifle, while separation and individuation—being on one’s own—brings anxiety and uncertainty. Clinicians are more likely to look at how early attachments, resentments, and identification with each parent based on such issues as their desired, if not envied, power. Thus notions of “penis envy” or “womb envy” that are salient in early childhood tend to be based less on anatomy than on the social roles and power of mothers and fathers.

For a number of reasons, psychoanalysis and sociology have been separate realms of theory and practice, though some people have worked at the intersections of the social and the personal; Freud himself offered various speculations. Today, however, those who do work at these junctures are more likely to work within the frameworks of object relations theory or self psychology. For example, Nancy Chodorow (1999) has looked at early gender differences in separation-individuation from early attachments to the mother. Young boys are able to make a more complete separation. Young girls are more likely to retain an attachment and identification with their mother, and thus “mothering is reproduced” in the shaping of their character. Jessica Benjamin (1988) has focused more on the need for recognition of self. Young girls deprived of recognition early in life are likely to seek it at any costs and are prone to masochism and humiliation to gain recognition from a man.

The most important legacy of Freudian theory in general and the Oedipus complex in particular has been to look at the emotional side of child development in general and gender socialization in particular. More sociological theories of socialization and personality development were influenced by Georg Simmel’s theory of dyads and triads in which the family structure alone gave rise to tensions and conflicts in which one party, the child, might foster conflict between parents, play off one parent against the other, or join one to gang up on the other. Much of what Freud observed was a result of the emotional aspects of the family structure. Charles Cooley, George Herbert Mead, and the symbolic interactionist traditions looked at language, play, role taking, and institutional aspects of socialization that fostered the “social self,” the active “I,” and the socially expected “me.” These approaches, however, often ignore the very powerful role of feelings and passions in the development and motivation of behavior. While few sociologists have tried to frame the major questions of civilization in terms of the Oedipus complex, some have considered some of the implications of Freud’s insights on gender, desire, and morality. For Philip Slater (1970), the repression of erotic desire to the mother, frustrating basic needs for dependency and community, has fostered a lonely society prone to aggression. Philip Rieff ([1966] 1987), on the other hand, felt that Freudian the-
ORY undermined the morally based repression that society required to maintain civility and its high culture. More recently, Lauren Langman (2006a, 2006b) has suggested that the macroeconomic consequences of globalization, often experienced as “castration” (powerlessness), have inspired various compensatory strategies such as religious fundamentalisms, which privilege patriarchy and celebrate male aggression.

The nature of the Oedipus complex still fosters lively debate, which will continue as long as people have children whose personal development involves ties to parents and intense feelings, emotions, desires, defenses, and ambivalence, all of which impact the nature of their adult personality.

OFFSHORE BANKING

The term offshore banking has no precise definition and thus means different things to different people. In part, confusion arises because the term is applied to two separate yet related phenomena. The generally accepted view is that offshore financial markets consist primarily of the various segments of the euromarkets, a “wholesale” or interbank market that is used primarily by commercial banks. The most important characteristics of offshore banking markets are their relative freedom from direct regulation and their specialization in wholesale banking transactions. Collectively these markets tend to function as a distribution mechanism for shifting funds from lenders to borrowers or deficit spending units on a global scale. Therefore, the economic rationale for offshore banks is that they perform this distribution function efficiently.

DESCRIPTION AND TERMINOLOGY

The offshore financial market is fully integrated, internally coherent, and global in reach yet is not literally offshore. It is situated in and between different types of financial centers, all of which are in major onshore cities such as London and Tokyo or in tax havens, some of which are called offshore financial centers (OFCs). That has led to some confusion. Intergovernmental bodies such as the International Monetary Fund (IMF) and the Bank for International Settlements (BIS) apply the term offshore banking in a more restrictive sense to describe financial activities that take place in an offshore banking sector of an OFC, or a tax haven in colloquial usage, such as the Bahamas and the Cayman Islands. However, only some countries employ the term offshore sector to describe a portion of their financial sectors. Two of the best known tax havens, Switzerland and Luxembourg, for instance, do not use that term. Intergovernmental bodies thus apply the term only to those countries. Academic scholars use the term more broadly to refer to all financial activities that take place in the unregulated offshore financial market.

The offshore financial market is not entirely unregulated: It is subject to so-called self-regulation based on market principles by the banks and other financial actors that use that market. The best known among a series of self-regulating agreements was the capital adequacy agreement, or the Basle Concordant of 1988, which was followed by Basle II, whose final accord was issued in 2004. In addition, for the sake of convenience, clearing goes through New York, giving the U.S. government some control over the market.

Transactions usually are thought to be offshore from the perspective of the host country even though the banks that conduct those operations are onshore. Among the reasons for this are the following:
• Some attempt usually is made to separate offshore from onshore banking activities and the rest of the domestic financial system by means of exchange control, regulation, tax incentives, separate accounting procedures, and the like.
• The institutions in the market tend to be classified as nonresident for balance of payments purposes.
• Transactions in these markets have a significant nonresident component. In some cases transactions are restricted specifically to nonresidents, but in other cases resident access to the market is permitted to varying degrees.
• Transactions in the offshore market are restricted primarily to foreign currencies.

SPONTANEOUS OFFSHORE BANKING SITES
There are three routes by which offshore centers are set up: the so-called spontaneous offshore sites, such as London and Hong Kong; international banking facilities (IBFs) such as New York and Tokyo; and tax havens, which include over seventy states. The offshore center in the city of London originally was called spontaneous because it allegedly was created accidentally as a result of attempts by the British government to reestablish London as the center of global financial activities after World War II.

The exact origins of the offshore financial market are in dispute, but it appears to have emerged in a set of fortuitous events. In late 1956, during the Suez Canal crisis and the ensuing run on the British pound, the British government attempted to defend the currency from devaluation by imposing restraints on sterling credits on countries that engaged in third-party transactions in the sterling area and by raising the bank rate from 5 percent to 7 percent. As a result, a number of second-tier merchant banks, such as the Bank of Latin America, that specialized in third-party international loans were faced with complete cessation of their business. In response, they began actively to solicit dollar deposits to use in trade credits to replace sterling credits. They have argued that the British government’s rulings explicitly prohibited the use of sterling credits in third-party loans but said nothing about other currencies, specifically American dollars. The British government allowed and perhaps encouraged the merchant banks to turn to American dollars; otherwise they would have gone out of business.

The little-known understanding between the Bank of England and the merchant banks produced a subtle but important reinterpretation of the purview of British sovereignty: It placed dollar transactions, along with all other third-party currency transactions, outside exchange rate regulation, reserve regulation, and any other regulation by the British state. However, because those transactions took place within the territorial boundaries of the United Kingdom, they were sheltered from the regulation of other states; they therefore were, de facto, under no state regulation, or “offshore.”

The new understanding was applicable only to third-party transactions, that is, cases in which British banks served as intermediaries between two non-British nationals using dollars or other foreign currencies. To ensure the legality of those transactions, British banks, who soon were joined by branches of American and other foreign banks in London, kept two sets of books: one for onshore financial transactions in which at least one party to the transaction was British and the other for offshore transactions when both parties were non-British.

INTERNATIONAL BANKING FACILITIES
An IBF is a more restricted type of offshore center in which, in contrast to spontaneous offshore centers, companies must apply for a license to trade. The first IBF was the Asian Currency Units (ACUs) set up in Singapore in 1968. The better known IBFs are situated in the United States.

The first New York IBF came about as the result of prolonged and complex battles between the U.S. Treasury, the Swiss government, and a number of Caribbean tax havens. The United States government had tried hard to deregulate the euromarkets in 1979. Failing that and with the active encouragement of the New York banking community, particularly Citibank and Chase, the U.S. Treasury concluded that rather than fight the onset of offshore centers, the United States stood to gain more by encouraging the formation of its own offshore centers. A swift about-face took place, culminating in the establishment on December 3, 1981, of a New York offshore market: the New York International Banking Facilities. A decade later more than 540 IBFs had been established across the United States to take advantage of those cost and tax benefits. New York had the largest number (over 250); California had 100 IBFs, and Florida had 80. However, as a result of their restrictiveness compared with other offshore centers, interest in IBFs waned. The New York IBF spawned the creation of the Tokyo IBF. In 1982 the Hosomi plan was put forward in imitation of the New York IBF to spur domestic liberalization in Japan.

TAX HAVENS
The third category of offshore financial centers is tax havens, of which there were seventy in the first decade of the twenty-first century. Tax havens are centers that offer an array of tax and regulatory incentives for nonresident investors and complete flexibility in the management of foreign assets. There are as many varieties of tax haven
laws as there are jurisdictions, but it is common practice to distinguish among four classes of tax havens: countries where there is no income tax and where foreign corporations pay only license fees; jurisdictions with low taxation, such as Liechtenstein and Jersey; countries where taxes are levied only on internal taxable events but not at all or at very low rates on profits from foreign sources; and jurisdictions that offer special tax privileges to certain types of companies and operations. Crucially, most tax havens maintain strict bank secrecy laws and prevent banks located in their territory from revealing the identity of account holders even to the tax haven government. Many tax havens have created provisions for trusts and other financial entities whose ultimate owners are difficult to identify. For these reasons tax havens are used not only for tax evasion and avoidance, but also for money laundering purposes and other criminal financial activities.

Tax havens are employed by the banking community for a number of interrelated reasons: avoiding current tax, preserving wealth, securing secrecy, avoiding regulation, and gaining easy access to the euromarkets. Banks tend to register high-volume, lucrative wholesale financial transactions through offshore subsidiaries as the financial equivalent of transfer pricing to reduce their tax bill. More important, tax havens are employed to help wealthy clients reduce current tax or preserve wealth or to secure secrecy. In addition, banks are able to avoid domestic regulation by diverting certain activities to their offshore subsidiaries. U.S. banks, for instance, employed offshore subsidiaries in the 1970s and 1980s to access other lucrative financial sectors, such as insurance and mortgages thus avoiding U.S. financial regulations.

Tax havens provide a cheap and easy way for resident companies or individuals to masquerade as nonresidents for euromarkets purposes; hence, a strong symbiotic relationship has evolved between tax havens and the euromarkets. In addition, tax havens permit companies to syndicate their profits worldwide in jurisdictions with zero or nearly zero regulation. Tax havens thus are used to accumulate dividends, interest, and other income. They also are used by multinational enterprises as central points for handling paperwork and preparing and processing trade documents. Many companies depend on tax havens for passage of title to goods to minimize red tape.

For all these reasons, tax havens have been an enormous success. On average 50 to 65 percent of all international banks’ net external liabilities were routed through tax havens between 1980 and 2004; approximately 27 percent of all foreign investments by multinational corporations are routed through tax havens. Havens such as the British Virgin Islands (6.7 percent) and the Cayman Islands (2 percent) are among the most important “for-}

eign” direct investors in China; they were second and seventh, respectively, in 2004.

**TYPES AND USES OF OFFSHORE FINANCIAL MARKETS**

Regardless of the historical and juridical origins of the different financial centers, they tend to be closely linked, with a division of labor among them. The literature distinguishes four types of offshore financial centers: Primary centers such as London and New York serve worldwide clients and act as international financial intermediaries for their market regions; booking centers such as Nassau and the Cayman Islands are used by international banks primarily as the location for “shell branches” to book both eurocurrency deposits and international loans; funding centers such as Singapore and Panama play the role of inward financial intermediaries, channeling offshore funds from outside their markets toward local or regional uses; and collection centers such as Bahrain engage primarily in outward financial intermediation. This hierarchy indicates the degree of specialization and interdependence among offshore centers.

The offshore financial market in the first decade of the twenty-first century included several markets: eurocurrency deposits, eurocurrency bank loans, euro notes, eurobonds, euro equities, and foreign exchange markets. The eurocurrency market grew very fast. According to the BIS, the gross size of the eurocurrency market increased from $US 12.4 billion in 1963 to $US 149.9 billion in 1972, $US 1,517.4 billion in 1982, $US 6,197.7 billion in 1992, and $US 24,026 billion in 2006. According to a BIS survey, average daily turnover in traditional foreign exchange markets is approximately $1,880 billion. Approximately 80 percent of all international financial transactions take place in this offshore financial market (BIS, Locational Banking statistics, 2006).

**EFFECTS ON THE WORLD ECONOMY**

The offshore financial market is therefore a secondary space for financial operations that has accelerated the transnationalization of the world economy. The development of offshore banking operations should be considered in the broader context of the general process of internationalization of economic activities involving trade. Because offshore financial markets have widened the access of companies to loan markets, it has been argued, they have brought down borrowing costs relative to the underlying level of interest rates. As a result of reduced costs, competition from offshore financial markets has forced the liberalization of onshore markets. As a result, only the imposition by some central banks of non-interest-bearing reserve requirements on domestic bank
deposits remains as a major domestic regulation that favors eurocurrency transactions. Because costs have fallen, companies can borrow in whatever market is most advantageous to them and swap the proceeds for the currency they need.

The apparent lack of regulation and control raises concerns about whether these markets have a capacity to create credit or money beyond the domestic banking systems and the extent to which they have diffused domestic monetary controls. To what extent have they contributed to currency instability? Although offshore finance is distinguished by a relative lack of state regulation and monitoring, there are degrees of regulation and monitoring. Besides the variations among financial centers that were noted above, several agreements reached by various standing committees that meet at the BIS under the aegis of the Governors of the Group of Ten have proved to be successful. The Basle Committee on Banking Supervision is the best known of those committees, and the Euro-currency Standing Committee is the oldest, having been set up in the early 1960s to monitor and assess the implications of the newly established eurocurrency markets.

The most important long-term impact of offshore finance may have occurred elsewhere. The term offshore evokes images of the high seas, of a world beyond borders. However, offshore financial transactions are very much onshore, conceived, organized, and handled in the traditional financial centers of London, New York, and Tokyo. Offshore banking therefore is not outside the state system but is a juridical realm marking the differential degrees of intensity by which states apply regulation and taxation. Offshore banking therefore denotes the bifurcation of the juridical space of sovereignty into mutually dependent relative spaces.

OGBU, JOHN U.
1939–2004

John Ogbu, one of the United States’s foremost educational anthropologists, studied the educational attitudes of marginalized youth, particularly highlighting the underachievement of African American students. Ogbu depicted blacks as being the victims of their own defeatist attitudes that have evolved over years of oppression. His work was and remains controversial.

Born to a farming family in a small village in Nigeria in 1939, Ogbu completed his BA (1965), MA (1969), and PhD (1971) all at the University of California at Berkeley. He was hired into the university’s department of anthropology and was promoted to professor in 1980. He died August 20, 2004, at the age of 64.

Ogbu was not the first to stress a victim blame analysis, but his theoretical propositions, written with such sophistication, elegance, and clarity, were easily translated into researchable hypotheses, and this explains why his ideas continue to generate research that both affirm and contest his stance. To Ogbu, low-income and privileged black youths shared a resistance to high achievement that is a result of the legacy of slavery as well as the racial oppression that was particularly acute up to the 1954 Supreme Court Brown v. the Board of Education of Topeka, Kansas decision calling for the desegregation of public schools. With the expanding opportunities achieved by blacks as part of the civil rights and black power movements of the 1960s and 1970s, Ogbu saw black resistance turn into an anachronistic coping mechanism (Ogbu 1995a; 1995b). He did not deny the effects of ongoing racism, but he felt blacks should recognize they were misreading the now more open and less oppressive U.S. society. Eschewing notions of genetic inferiority, Ogbu argued that the larger society and the black community itself had to work to help turn black educational attitudes from disengagement to an active pursuit of excellence and hope.

Because Ogbu’s theories touched on educational disadvantage found across the globe, his books, chapters, and articles were translated into Spanish, Mandarin, Italian, French, German, and Croatian. Although his analysis
placed heavy emphasis on the educational attitudes of individual children and their parents, his overall perspective was ecological, and he demonstrated that educational attitudes held by children were the result of complex, daily interactions within the family, neighborhood, community, workplace, and nation. Overall, his work reflected strong structural-determinism themes. His *Minority Education and Caste: The American System in Cross-Cultural Perspective* (1978) argued that the same kinds of social divisions between white and black societies in the United States are replicated in caste-society interactions across many cultures. His work with Signithia Fordham (1986) helped popularize concepts such as the burden of “acting white” and “black oppositional identity,” and his career culminated with a stunning text, *Black Americans in an Affluent Suburb: A Study of Academic Disengagement* (2003), in which he showed that both low-income and middle-class black youths are hesitant to embrace academic achievement.

Much of Ogbu's research was grounded in small-scale ethnographic studies covering a limited number of participants and a constrained number of research sites. Using large samples collected in schools across a wide range of sites, other researchers have failed to find empirical support for Ogbu's key premises (Ainsworth-Darnell and Downey 1998; Cook and Ludwig 1998; Spencer et al. 2003). Even Ogbu's attempt to link contemporary trends in black education with a “legacy of slavery” has been shown to have no basis in historical fact and research (Anderson 1988; Spencer et al. 2003). It has been suggested that the small scale of Ogbu’s research exaggerated the significance of educational attitudes held by only a fraction of black students while overlooking or dismissing attitudes held by the overwhelming majority of students that undercut his pejorative thesis (Foster 2004). To the very end, though, Ogbu held true to his perspective, and he accused his critics of the worst kind of cultural romanticism (2003), although he never produced findings from any large-scale study that refuted his critics’ charges. Although the trend in the empirical literature is to move away from Ogbu’s theorizing, figures in the popular debate about black achievement attitudes—such as the comedian-turned-social-critic Bill Cosby and the celebrated radio-television commentator Juan Williams—continue to accord Ogbu’s work considerable credence (Williams 2006).

OKUN’S LAW

In 1962 the Council of Economic Advisers (CEA) to U.S. president John F. Kennedy (1917–1963) was trying to persuade him to stimulate an underperforming economy. Council members explained that the actual output of the economy was far below its potential or full-capacity output level. As a result, unemployment was excessive. An economy with high unemployment was not only socially unjust and oppressive, but also wasteful and inefficient. The unemployment rate was only the tip of the iceberg of a depressed economy troubled by enforced part-time work, lost overtime and promotion opportunities, discouraged job seekers, greater poverty, declining productivity, and rising government deficits. While there appeared to be a strong case to persuade policymakers of the benefits of reducing unemployment, there was only conjecture about the magnitude of the likely output and income gains. A more precise estimate of these gains was needed to clinch the argument.

The CEA settled on 4 percent unemployment as consistent with potential output. The issue was then how to use this unemployment figure to work out the value of the gap between actual and potential output that needed to be closed. The economist Arthur Okun (1928–1980), then working for the CEA, found a good shorthand approximation for the complicated interaction between employment and output: there was a three-to-one link between output and the unemployment rate so that each extra percentage point in the unemployment rate above 4 percent was associated with a 3 percent fall in output (or real gross domestic product [GDP]). This then yielded the following relationship:

\[ P = A [1 + 0.03 (U - 4)] \]

So if unemployment \((U) = 4\) percent, then potential GDP \((P)\) equaled actual GDP \((A)\). If \(U = 5\) percent, the estimated gap between what the economy was capable of producing and what it was actually producing was 3 percent of GDP. This then provided an estimate of how much extra output and income needed to be generated to get the economy healthy again.

The relationship between unemployment and output that Okun had discovered was called Okun’s law. The economist James Tobin (1918–2002) regarded it as “one of the most reliable and important empirical regularities of macroeconomics” (Perry and Tobin 2000, Preface), and it provided a major part of the empirical justification for Kennedy’s tax cuts to stimulate the economy (Prachowny 2000). Okun’s law did not have precise theoretical underpinnings. It was a widely used rule of thumb. Okun had tried alternative ways to estimate the relationship but always got roughly the same answer, and he was delighted how well it stood up over time.

THE REACTION TO OKUN’S LAW

High-output growth is typically associated with a fall in unemployment as firms hire more workers to produce output. However, output growth must at least cover the natural increase in the labor force and the increased productivity of labor to prevent unemployment from rising. Output needs to grow in excess of this rate in order to reduce unemployment. Yet there may be lags in the relationship so that even if output growth rises, firms may delay new hiring until they are certain that the increased growth will persist. Furthermore, the nature of the unemployment will determine how easily it can be absorbed into new work opportunities. If it is cyclical unemployment (associated with temporary layoffs), then it will be absorbed more rapidly than structural unemployment (associated with jobs permanently relocated elsewhere in other industries or with a different skill mix). Even then an increased labor force participation rate, from those formerly outside the labor force, will mean that unemployment may not immediately fall. The relationship then is a very complicated one, and Okun’s law is only a rough forecasting tool.

Okun’s relationship will vary from country to country and over time. Empirical studies suggest that the Okun’s law coefficient increased over the 1981 to 2000 period compared to the 1960 to 1980 period. International comparisons find that the coefficient varies considerably across countries, with Japan in particular being an outlier, reflecting the different labor market arrangements in that country. Research has also focused on getting better estimates of the relationship using more sophisticated econometric techniques and alternative empirical specifications, and correcting for various biases in the estimation. Other studies have concentrated on breaking the relationship into its component parts or have used different measures of unemployment, such as the constant weighted unemployment rate, to account for differences in the composition of the labor force. Various lagged output measures have often been used. Some studies claim that the output-employment ratio is asymmetric; in other words, cyclical unemployment is more sensitive to falls in output growth than increases. There are even skeptics who dismiss concepts such as potential output, the output gap, and the full-employment target altogether and argue that governments should not be in the business of actively managing the economy.

Paul Samuelson acknowledged Okun as the wisest and most creative economic policy adviser of his time. Edmund Phelps called him the foremost practitioner of macroeconomics in the United States. Okun attempted to translate theoretical ideas and concepts into operational guides or computational shortcuts that would be of direct use to policymakers. His widely used rule of thumb has
remained one of the most enduring stylized facts in macroeconomics. It continues to attract the interest of applied researchers and features in most macroeconomics textbooks, and it is through this “law” that generations of students come across Okun’s name.

OLIGARCHY

The term oligarchy refers to a form of government in which political power is in the hands of a small minority. The word oligarchy derives from the Greek word oligarkhia (government of the few), which is composed of oligoi (few) and arkhein (to rule). This definition does not necessarily distinguish oligarchy from other forms of government. Autocracy, for example, can be viewed as a form of oligarchy in which “the few” refers to a single individual, though autocracies, especially when they take the form of dictatorships, have commonly been associated with greater use of coercion. Democracy, some argue, is also characterized by a “rule of the few” because most political decisions are made by a small section of society. The key factor differentiating oligarchy and democracy is the fact that in democracy political decisions are made by representatives who can be voted out of office by the citizens in regularly scheduled elections. Direct democracy, where the people decide on policies without the intermediation of representatives, is an exception. Therefore, it can be useful to think of the different types of government as being located along a continuum that runs from autocracy to direct democracy. Furthermore, oligarchies are not confined to national politics; oligarchies can also emerge in local government (e.g., Hunter 1953) or in other organizations, such as labor unions.

THE IRON LAW OF OLIGARCHY

The most influential treatment of the politics of oligarchy is Political Parties (1911) by German social scientist Robert Michels (1876–1936). The focus of Michels’s work was the German Social Democratic Party, but his analysis had clear references to other types of social institutions, including national government. Michels’s conclusions were highly pessimistic from a democratic point of view. He argued that the necessity of organization for any large-scale social institution would sound the death knell for democratic governance. Famously, Michels went so far as to state, “Who says organization, says oligarchy” (1962, p. 365). The need for organization concentrated political power in the hands of a select few whose position at the apex of the organization served to solidify their standing. In Michels’s view, the advantages conferred upon the leaders of the organization eliminated the possibility of democratic control through leadership elections. These advantages included greater access to information, greater ability to communicate with the organization’s members, and the opportunity to develop political skills. Combined with the “incompetence of the masses,” evidenced by a lack of participation by ordinary members, which Michels saw as being due to the members’ lower degree of education, the division of labor, and organizational obstacles, the political power of the leadership was ensured.

Differences in knowledge and education also gave the appearance that the division between the leaders and the led was natural. If democratic government is defined as a form of government that serves the interests of its members, rather than being defined in procedural terms, nothing thus far suggests that democracy is impossible. However, the final component of Michels’s theory was that the interests of the leaders and the members would inevitably diverge. As the heads of the organization, the leaders’ interests become identified with their institutional position rather than the interests of the organization’s members. The leaders’ primary concern becomes protecting their position and serving their own ends using the organization as their means.

Despite Michels’s pessimistic conclusion about the prospects of democracy, it appears that relatively few governments identified as oligarchic in the literature followed the route he described. Instead, oligarchies have appeared as a consequence of, for example, the devolution of monarchical rule (e.g., in England under King John in the thirteenth century) or the concentration of economic influence (e.g., in Florence around the turn of the fifteenth century and in Chile in the 1830s).

RESEARCHING OLIGARCHY

Since Michels’s seminal contribution, there have been few systematic studies of the politics of oligarchy. There are
several reasons for why this has been the case. First, many of the issues raised by Michels are not specific to oligarchy as such but have far wider applicability. Representative government has been analyzed extensively in the context of democratic governments. Similarly, whether ordinary members can control their leaders is taken up in the literature on principal-agent theory. Both issues are at the core of Michels’s argument. Second, while the term oligarchy is commonly used, there exists no clear, universally accepted definition of oligarchy in the literature (Payne 1968; Leach 2005). Most scholars agree that oligarchy involves the concentration of political power in the hands of a minority, but this form of government has few other universally accepted defining characteristics. Third, because oligarchy is not necessarily seen as incompatible with (free) elections, the line between oligarchy and democracy becomes blurred. The most frequently cited factor distinguishing oligarchy from democracy is that admission into the class of oligarchs is restricted in some manner to a subset of the citizenry. The Greek philosopher Aristotle (384–322 BCE) classified oligarchies on the basis of types of restrictions on participation in government, where participation depended on property qualification or heredity (Whibley 1896). South Africa during the apartheid era, where the majority was disenfranchised on the basis of race, serves as an example of another possible type of restriction.

The failure to settle on a definition of oligarchy means that comparative studies, such as The Logic of Political Survival (2004) by Bruce Bueno de Mesquita, James Morrow, Randolph Siverson, and Alistair Smith, provide perhaps the most general insights into the politics of oligarchies. Rather than classifying governments as autocratic, democratic, or oligarchic, Bueno de Mesquita and his coauthors instead focus on the size of the group that has a say in the selection of the government or leader and the size of the coalition that the government needs to stay in power. Bueno de Mesquita and colleagues find, for example, that the characteristics associated with oligarchies (i.e., smaller coalitions) tend to reduce economic growth and government expenditures but to increase corruption.

The issue of membership in the governing class also looms large in accounts of the decline of oligarchies. J. Mark Ramseyer and Frances Rosenbluth’s (1995) account of Japan’s Meiji oligarchy highlights two problems an oligarchy must solve to survive: it must prevent the membership from being expanded, and, at the same time, it must provide for rules of succession. Ramseyer and Rosenbluth show that oligarchies may be vulnerable to competition for political influence among the oligarchs, which may induce them to mobilize previously excluded sections of society. For the same reason, oligarchies may be unable to agree on institutions that govern succession within the oligarchy. In the Soviet Union, by contrast, the Communist Party provided institutions that checked the actions of the oligarchs, although the rules guiding succession were somewhat ambiguous (Hammer 1990).

OLIGARCHY, IRON LAW OF

Coined by the German sociologist Robert Michels in his 1911 monograph Political Parties, the Iron Law of Oligarchy refers to the inbuilt tendency of all complex social organizations to turn bureaucratic and highly undemocratic. According to Michels, even the left-wing parties of Western Europe in the pre–World War I era, which were programatically committed to mass democracy, popular participation, and equality within their ranks, tended to become de facto oligarchies. In spite of their revolutionary manifestos and formally democratic constitutions, the labor parties of his day were dominated by demagogic ruling cliques with an interest in the perpetuation and growth of the organization itself rather than in its proclaimed ideological aims. As an especially ironic example, he noted that in a fundamentally democratic
organization such as his own German Social-Democratic Party (SPD)—just as in the traditional conservative parties—only a few people in executive positions actually held power and made all the important decisions. The SPD leaders, Michels argued, came to value their own prominent status and social-mobility rewards more than any commitment to the official goal of emancipating Germany’s “industrial proletariat.” Inevitably, their actual policies became more conservative and accommodationist seeking parliamentary compromise with the imperial authorities of Wilhelminian Germany in order to preserve the party, rather than endanger it by any confrontation in the streets. Eventually, the SPD leaders gained real legislative power and public prestige, but instead of serving the collective will of the mass membership, they were in fact dominating and directing it. For the numerically small party elite, the SPD as an organization became an end in itself, rather than a means to a revolutionary end: “It is organization which gives birth to the domination of the elected over the electors, of the mandatories over the mandants, of the delegates over the delegators. Who says organization, says oligarchy” (Michels [1911] 1968, p. 365).

Michels based his fatalistic theory on empirical observation. First of all, the day-to-day administration of any large-scale, differentiated bureaucratic organization such as the SPD by the rank-and-file majority was impossible. Given the “incompetence of the masses,” there was a need for full-time professional leadership and top-down guidance. In theory, the SPD leaders were subject to control by the rank-and-file through delegate conferences and membership voting, but in reality they were firmly in command. The simple organizational need for division of labor, hierarchy, and specialized leadership roles meant that control over the top functionaries from below was “purely fictitious.” The elected leaders had the experience, skills, and superior knowledge necessary for running the party and controlling all formal means of communication with the membership, including the party press. While proclaiming their devotion to the party program of social democracy, they soon became part of the German political establishment. The mass membership was unable to provide an effective counterweight to this entrenched minority of self-serving party officials, who were more committed to internal organizational goals and their own personal interests than to radical social change. Michels also felt that these inevitable oligarchic tendencies were reinforced by a mass predisposition for depending upon and even glorifying the party oligarchs, because the rank-and-file had a basic psychological need for hero-worship: “Though it grumbles occasionally, the majority is really delighted to find persons who will take the trouble to look after its affairs. In the mass, and even in the organized mass of the labor parties, there is an immense need for direction and guidance. This need is accompanied by a genuine cult for the leaders, who are regarded as heroes” (Michels [1911] 1968, p. 88).

The Iron Law of Oligarchy was thus a product of Michels’s own personal experiences as a frustrated idealist and a disillusioned social-democrat. His Political Parties was based upon an empirical study of the SPD and a number of affiliated German trade unions. He observed firsthand that the ordinary members of these working-class organizations were practically excluded from the decision-making process, which was effectively in the hands of the more experienced and skilled leadership cadres. This sociological analysis made Michels increasingly pessimistic about the possibility of mass democracy, until he eventually embraced the “elite theory” of his Italian contemporaries Vilfredo Pareto (1848–1923) and Gaetano Mosca (1858–1941). In a total break with the past, he also adopted Italy as his new homeland and Italian fascism as his political ideal, becoming one of Benito Mussolini’s academic acolytes and favored ideologues.

Democratic theorists have ever since questioned whether the oligarchic tendencies described by Michels’s overdeterministic model are indeed so universal, inevitable, and immutable to be labeled an “iron law.” Michels’s theory has been applied to modern-day labor unions, trying to demonstrate how, as bureaucratic organizations, they have become ends in themselves rather than a means to an end. Critics, however, have rejected Michels’s message that “organizational parties” destroy democracy and turn it into oligarchy. The eminent Italian political scientist Giovanni Sartori, for one, argues that Michels may well have formulated an iron law of bureaucracy, but only a “bronze law” of oligarchy, mistakenly seeking “democracy in structures, not in interactions,” and ignoring the real difference between democracies and nondemocracies (Sartori 1987, pp. 149–151). In contrast, students of post-Communist politics have noted that too many respondents in public-opinion surveys claim to have the same or even less influence on government today than under Communist rule. In this empirical sense, the Iron Law of Oligarchy is difficult either to confirm or to refute decisively.

OLMECS

“Olmec” is the name used to designate an archaeological culture centered on the lowlands of the states of Veracruz and Tabasco on the Gulf Coast of Mexico. Olmec culture, which flourished from 1200 to 400 BCE, was the first complex culture with monumental art and architecture in ancient Mesoamerica (Mexico, Guatemala, and Belize). Later Mesoamerican cultures such as the Aztec, Maya, and Toltec built on the achievements of the earlier Olmec, especially in the areas of social organization, monumental artistic expression, and religious thought.

The hot, humid lowlands of Veracruz and Tabasco had been little explored in the 1930s when archaeologists began to uncover signs of a complex archaeological culture in the area. The initial trait that set Olmec culture apart was the presence of stone monuments that proved to be the earliest examples of monumental art in Mesoamerica. Shortly after these discoveries, archaeologists found examples of monumental architecture in the form of the Mesoamerican truncated pyramid. An early example, from the site of La Venta, rose to a height of 98 feet and was one of the largest buildings in Mesoamerica at the time. Work from the 1960s through the 1990s at the site of San Lorenzo revealed monumental sculpture together with early evidence of a residential palace, complete with a stone drainage system and massive stone columns at the entryway. Major stone monuments also survive at Laguna de los Cerros, a little explored Olmec center. Access to stone in a region with few stone resources must have been a sign of prestige, and the presence of an elaborate palace structure demonstrates that Olmec society was clearly stratified.

Later Olmec also treated access to jade as a principal elite marker. The Olmec traded for the material across a major portion of Mesoamerica, as most Olmec jade is thought to originate in the highlands of Guatemala. While the physiognomy of the colossal heads is sometimes cited as proof of transatlantic contacts, there is no clear archaeological evidence that the Olmec traded with or were contacted by Africans or any other peoples outside of Mesoamerica and Central America.

The iconography of Olmec monumental stone sculpture is varied but may be characterized by its interest in portraying rulership. Colossal stone portrait heads of the rulers were set up in the center of Olmec cities, while the earliest stelae bear the image of humans performing rites clearly associated with rulership in later Mesoamerican cultures. Massive stone thrones also point to the close relationship between monuments and rulership. A particular interest in the depiction of infants is evidenced in both small-scale ceramic and monumental stone sculpture. Other motifs and a set of supernatural beings were shared with peoples all over Mesoamerica from the earliest Olmec times. The Olmec developed hieroglyphic writing before other literate Mesoamerican cultures such as those of Monte Albán or the Maya.

Olmec centers, the largest of which held perhaps 3,000 inhabitants, were based on the highly productive agriculture possible around the waterways of Veracruz and Tabasco. Control of this land may have lead to early stratification, and the presence of extensive waterways eased travel and trade in an area that had no beasts of burden. San Lorenzo, the earliest Olmec center (flourished 1200–900 BCE), as well as its successor, La Venta (flourished 900–400 BCE), fit this pattern.

OLYMPIC GAMES

The Olympic Games are an international sporting event held quadrennially in different venues. The date of inception remains a point of conjecture among historians, but it is generally accepted that the Olympic Games found their genesis in Olympia, Greece, in 776 BCE and survived...
Olympic Games

in attenuated form until 393 BCE. Inspired by the ancient Greek festival, the modern Olympic Games were revived in 1896 by Baron Pierre de Coubertin, a French nobleman who envisaged that the Games would foster a religion of patriotism by directing the new power of national identity into constructive and peaceful channels. Initially, only amateur athletes were permitted to compete in the Olympics; professional athletes were not allowed to compete until the 1970s when the amateurism requirements were extracted from the Olympic Charter. The revival of the Olympic Games was held in Athens, Greece. The Games attracted a relatively small competitive field, with about 240 athletes competing in 43 events.

In the early years of the twentieth century, the International Olympic Committee encountered an array of difficulties with the hosting of the Games. The subsequent two celebrations that followed the Athens Games failed to command popular support, partly because they were crossed with, and effectively eclipsed by, the World’s Fair Exhibitions in Paris (1900) and Saint Louis (1904). The 1908 Games, though originally awarded to Rome, were held in London. The majority of the competing countries selected national teams to participate in the London Games, and the athletes were paraded by nation at the opening ceremony. The Olympic Games had institutionalized the “nation” in international athletics. After the 1912 Olympic Games, held in Stockholm, the Olympic movement entered a period of upheaval. De Coubertin may have seen the Olympics as an agent of international peace in a world moving inexorably toward war, but the ideal of the Olympics as an event that could prevent war proved ill-founded. The Games scheduled for Berlin in 1916 were abandoned because of World War I, and two other Olympiads passed without Games in 1940 and 1944 as a result of World War II.

In the aftermath of World War I, the 1920 Games were awarded to Antwerp as a mark of respect for the Belgian people after the anguish that had been inflicted on them during the war. The 1920 opening ceremony was notable for the introduction of the Olympic flag, the release of doves as a symbol of peace, and the presentation of the athletes’ oath. The introduction of the flag, representing the unity of the five continents, and the symbolic release of doves also reflected the idyllic vision of the Olympic movement as standing for international peace and unity.

However, it was also in the interwar period that Olympic sport became symbolic of national struggle, with participants as representatives of their national groups. Throughout the twentieth century, John MacAlloon argues, “a nascent athletic nationalism was already undermining the Olympic ideal” (1981, pp. 258–259). A notable instance of this was Adolf Hitler’s use of the 1936 Olympic Games to enhance his control over the German populace and legitimize Nazi culture. The opening ceremony designed for those games was a shrewdly propagandistic and brilliantly conceived charade that reinforced and mobilized the hysterical patriotism of the German masses. The Berlin Games have also become closely associated in the popular imagination with the African American athlete Jesse Owens. Against a background of Nazi efforts to manipulate the Games to demonstrate the racial and athletic superiority of the Aryan race, Owens won four gold medals at the first Olympic Games to be broadcast on a form of television. The Berlin Games demonstrated how the hosting of the Olympic Games could be manipulated to provide a benign and uncritical backdrop for the parade of national identity.

Another political incident involving African American athletes occurred at the 1968 Summer Olympics in Mexico City. Two African American track-and-field athletes, Tommie Smith and John Carlos, bowed their heads and raised a black-gloved power salute on the victory podium during the playing of “The Star-Spangled Banner.” USA Olympics officials asserted that the athletes should not have used the Games as a platform to air their political grievances, and the two athletes were immediately suspended from the U.S. team and banned from the Olympic Village. Politics was also to cast its shadow over the 1972 Summer Olympics in Munich, West Germany, when members of the Israeli Olympic team were taken hostage by the Palestinian terrorist organization Black September. The terrorists killed eleven Israeli athletes and one German police officer in an event that is conventionally referred to as the Munich Massacre.

The 1980 Olympics in Moscow were arguably the most political in the history of the Games and reflected the extremes of nationalism that had emerged as a result of the renewed cold war struggle. In 1980 the United States and sixty-four other Western nations refused to compete at the Moscow Olympics that year because of the Soviet invasion of Afghanistan. The boycott reduced the number of nations participating to only eighty, including only sixteen Western nations—the lowest number of nations to compete since 1956. The Soviet Union and fourteen Eastern bloc countries (Romania was the exception) retaliated by boycotting the Los Angeles Olympics in 1984.

In the Olympic arena, encircled by flags of various nations, the political symbolism of sport is most evident. Young nations make use of the nationalist symbolism of sport to gain recognition on the world stage; established nations do so to demonstrate their strength and prowess. The media make use of sport to construct a “battle” among nations, giving individuals a public spectacle at which they can cheer on their compatriots. The central
role of the Olympics as a forum where new nations can gain acceptance is also clear from the number of nations taking part. In Antwerp in 1920, twenty-nine nations competed; by the Athens Olympics of 2004, that number had risen spectacularly to 201. The importance of the Olympic Games to cultural unity and national identity lies not only within the event as staged but in the sporting occasion as an international spectacle. Beyond the demonstration of physical strength and skill, Olympic sport as collective ritual, highlighting concepts of leadership and heroism, has become part of the language of nationalism.

**ONE-PARTY STATES**

One-party states, or single-party states, are nation-states where only one specific political party has the monopoly of political power. One-party states are autocratic and nondemocratic political regimes. Examples of one-party nation-states are North Korea, Cuba, and China. In these countries the Communist Party has the legal monopoly of representing the whole of society in politics on the basis of a Communist constitution. Non-Communist one-party states can be found mainly in Africa, but these political systems are mostly linked with weak or failing states, whereas Communist single-party states are combined with a strong state apparatus and a highly centralized bureaucracy.

The main difference between a one-party state and a dominant party state is that one party has the monopoly of political representation of society in the former and a strong party is dominating within a multiparty system in the latter. A single-party nation-state is always a non-democratic political regime. A dominant party state can be either a democratic regime or a hybrid regime, combining elements of democratic and autocratic political systems. In a dominant party state there is one strong, major political party, which dominates several small and minor political parties. Historical examples of democratic dominant party states are Italy and Japan after 1945 and India after gaining independence from the British Empire in 1947. An example of a hybrid dominant party state with democratic as well as autocratic elements is the Russian Federation under President Vladimir Putin (2000–2007), with “United Russia” as the dominant political party.

One-party states are characterized by one single party representing the whole of society, assuming that there are no particular social interests, only a general and unified political will, representing a dominant and supposedly superior social class, the working class. Communist one-party states like North Korea, Cuba, or China are characterized by long-term autocratic and charismatic leaders such as Kim Il Sung (1912–1994) in North Korea, Fidel Castro (1926–) in Cuba, and Mao Zedong (Tse-tung) (1893–1976) in China. For many decades the one-party regime in all three countries had leaders with a cult of personality, and the nations displayed gigantic portraits and statues to create a larger-than-life public image for their rulers. In the mid-2000s North Korea and Cuba were examples of unchanged Communist regimes with a centrally planned economy. China represents a Communist one-party state, which is changing the economic system from a Communist command economy to a capitalist market economy. One positive aspect of one-party states is the centralization of political power, which facilitates structural changes of the economy toward a free market economy, like in contemporary China. Negative aspects of single-party states are the lack of democratic and human rights as well as the absence of social liberties and political freedom. One-party states can be—due to the lack of democratic checks and balances—irrational actors in international politics, when their autocratic leaders decide.
a certain course of foreign policy. The end of the rule of the current dictators in Cuba and North Korea might be a chance for social forces and social movements in these remaining Communist states to commence a transformation toward democracy and a free market economy. China is already on a long march toward a capitalist economy with an uncertain future of its current one-party state.

OPEN MARKET OPERATIONS
Open market operations are purchases and sales of securities between a central bank (for example, the Federal Reserve in the United States, the Bank of England in the United Kingdom, and the European Central Bank in most of Europe) and the banking system. These securities are usually government-issued (mostly bonds on government debt), although they can include private and foreign securities, and gold. When the central bank buys a security from a bank it increases the bank’s asset position with respect to the central bank. This allows the bank to make more loans to its clients, thus increasing the overall amount of money available to the public. By contrast, a central bank sale of securities has the converse effect.

Banks holding excess asset positions with the central bank can loan these surplus funds to banks with deficit positions. These trades are usually in the form of overnight loans at an interest rate negotiated individually between the parties of the agreement. For example, in the United States such loans are called federal funds and the volume weighted average of the interest rate charged is called the federal funds rate. In addition, most central banks have standing deposit and lending facilities so that banks that cannot find favorable counterparties can trade with the central bank instead. Standing facilities therefore limit the variability of the overnight rate charged in bilateral trades between banks.

Open market operations allow the central bank to modify the banking system’s overall asset position and, hence, to control the average interest rate charged on these overnight loans. This overnight rate then serves as a reference rate for loans at longer maturities. For example, to make a borrower indifferent to the choice between a two-day loan and a one-day loan that is rolled over the next day, the loan rate charged on the two-day loan should be an average of the rates charged on the two one-day loans. Similar arbitrage arguments (with some adjustments for risk and uncertainty about the value of one-day loans in the future) link interest rates at different maturities (often referred to as the term structure) with the overnight rate that the central bank manages through open market operations. Ultimately, fluctuations in longer-term interest rates affect investment decisions and the future level of economic activity.

In most modern economies, independent central banks are commissioned with two main responsibilities: (1) the conduct of monetary policy, broadly meant as managing the amount of money in the economy so that it is compatible with price and exchange rate stability, and economic growth; and (2) regulation of the banking and financial systems. The central bank is the banking system’s banker (as well as the government’s). Its ability to conduct open market operations and modify the overall asset position of the banking system allows the central bank control over the economy’s money supply and the overnight interest rate. Insofar as high levels of economic activity can generate inflation and overnight rates are linked through arbitrage to long-term rates (which ultimately determine investment and the overall level of economic activity), open market operations are the main vehicle by which a central bank implements its monetary policy objectives.

OPERANT CONDITIONING

Learning is an important topic for the social sciences. It can explain much of development, for example, and can be used in many applied settings (such as educational or clinical). There are various perspectives on learning. One of the most useful involves operant conditioning.

An operant is a voluntary behavior that is used in order to obtain a reinforcer or avoid a punisher. Operant Conditioning uses reinforcement and punishment systematically to facilitate learning. Its unique foci include, first, its focus on voluntary behaviors ("operants"), and second, its emphasis on the consequences of behavior. Other learning theories emphasize antecedents rather than consequences and involuntary behaviors, or reflexes, rather than operants. The Classical Conditioning perspective, for instance, focuses on antecedents and reflexes. The founder of Classical Conditioning, Ivan Pavlov, used a bell as an antecedent stimulus in his well-known research with dogs. These dogs salivated after the ringing of the bell had been repeatedly associated with meat powder. Salivation is of course a reflex. Though this emphasis on reflexes implies that Classical Conditioning may not be as useful as Operant Conditioning, it did influence the development of the Lamaze birthing technique and has been adapted to the systematic desensitization of phobias and other problems that involve physiology and reflexes.

Another perspective, called Social Learning theory, is more consistent with Operant theory than is Classical Conditioning. It emphasizes modeling and observational learning but it recognizes the impact of consequences. A child might observe a hero on television, for example, who is richly rewarded for some altruistic behavior, and although the child watching the television is not reinforced, the child imitates the hero. Observational learning of this sort is sometimes described as "vicarious reinforcement."

Reinforcement makes operant behavior more likely to occur in the future. Punishment makes operants less likely to occur. Reinforcement can be used in an operant procedure known as shaping. Here reinforcement is given to behaviors that increasingly resemble a target behavior, and gradually the individual will in fact display that target behavior. It is sometimes called the Method of Successive Approximation. Fading involves reinforcing one behavior simultaneously with prompts or assistance of some kind. The assistance is gradually withdrawn, or faded, until the behavior is emitted without any prompts. Undesirable behaviors can be eliminated from behavioral repertoires by punishing them. Alternatively, it is sometimes more appropriate to identify the reinforcers that are supporting the undesirable behavior and simply eliminate them. In this fashion, punishment is unnecessary. If behavior is not supported by reinforcement, it becomes extinct. This is the rationale for time-outs; individuals are placed in a setting that does not allow them to receive reinforcement, nor support inappropriate behaviors.

Consequences are not always effective in controlling behavior. Indeed, one of the most important steps when using operant procedures involves the accurate identification of reinforcers and punishers. There are many idiosyncrasies; what controls the behavior of one person often has no impact on another. The effectiveness of consequences is in part determined by the type and amount given, but also by deprivation (hunger), the gradient (the interval between the behavior and the consequence), and the schedule (the number of behaviors that must be emitted to earn a reinforcer). In general, a shorter interval ensures that consequences are maximally effective. Early on it is also important to use a continuous schedule, with a one-to-one ratio (every single instance of the behavior earns the consequence). Larger ratios are useful to program generalization and maintenance. It is typically best to start with a continuous schedule, but then thin the schedule such that the individual may emit two, then three, then five, then ten behaviors to earn one reinforcer. Similarly, variable schedules can be used to ensure that behavior is resistant to extinction. In a variable (or intermittent) schedule the ratio of behaviors to reinforcers fluctuates (3:1, then 5:1, then 2:1, then 7:1, and so on). B. F. Skinner demonstrated each of these operant concepts using highly controlled laboratory experiments, typically with subhuman species.

At one point Skinner drew from operant principles to develop a highly controlled crib for his own daughter. It kept her environment at an ideal temperature, with controlled lighting and visual stimuli. This reflects Skinner’s emphasis on environmental control. The environment sometimes influences behavior in ways that one does not even notice, such as visual distraction or temperature, and sometimes the environmental influence takes the form of
obvious consequences to one’s actions, such as reinforcers and punishers. Skinner felt that one could retain free will only if one maintained an awareness of the environmental and experiential influences on one’s behavior. The apparatus just described is sometimes called a Skinner Box, though that name is also sometimes used to describe the operant chamber in which rats are trained via reinforcement. Operant chambers automatically monitor and reinforce particular behaviors (for example, pressing down on a bar). They provide a high level of experimental control, which was typical of Skinner’s work. He felt that objectivity and experimental control were necessary if psychology was to be scientific. He once stated that sciences are only valid if they can “predict and control.”

Additional research by Skinner and others has demonstrated that operant conditioning is highly effective when used systematically in educational or clinical settings. In fact, according to Skinner, operant conditioning also occurs spontaneously in the natural environment. Parents, for example, may reinforce or punish behavior without really intending to do so (or at least without relying on operant theory to make their decisions). Skinner’s 1948 novel, *Walden Two*, describes a segment of the population that employs operant principles in a kind of utopia. The key idea is that consequences dramatically influence behavior and, as noted above, in order to exercise free will, people should be aware of operants’ effects and use them in a systematic and beneficial fashion.

**OPERATION BOOTSTRAP**

Operation Bootstrap was a development policy implemented in Puerto Rico after World War II (1939–1945) that achieved rapid industrialization of the island’s economic structure. Critics, though, contend that the policy brought about steep agricultural decline and dislocation, large-scale emigration, and increased economic dependency.

Puerto Rico, a colony that the United States took from Spain during the 1898 Spanish-American War, had until World War II an agricultural economy plagued with severe unemployment and poverty. Teodoro Moscoso (1910–1992), the first director of Puerto Rico’s Economic Development Administration (popularly known as Fomento), and Luis Muñoz Marín (1898–1980), Puerto Rico’s first elected governor, concluded that the best solution to the island’s development problems was to promote industrial investments from the United States.

They proposed using tax exemptions, approved by Puerto Rico’s legislature in 1947, to entice American corporations to set up factories on the island. Further attractive conditions for corporate investment were low labor costs, laws allowing products to enter the United States duty free, and the security of operating in an American-controlled territory.

Muñoz Marín first used the name *Operation Bootstrap* in 1949 in testimony before the U.S. House of Representatives Committee on Public Lands. “We are trying to lift ourselves by our own bootstraps,” he stated. The name, though, was a disingenuous misnomer, in that it metaphorically implied endogenous development when the plan in reality relied upon foreign investment. The more accurate translation for the program’s name in Spanish, *manos a la obra*, is “let’s get to work.”

In order to further its campaign to attract U.S. industrial investments, Fomento employed American advertising agencies, including one headed by David Ogilvy (1911–1999), to create a positive image of Puerto Rico and the idea that the island was undergoing a renaissance. American corporations responded quickly. In its first phase, which lasted up to the 1960s, Operation Bootstrap attracted low-wage, labor-intensive industries, particularly in textiles and clothing. The subsequent second phase attracted more capital-intensive industries in petrochemicals, oil refinement, and pharmaceuticals.

At the high point of Operation Bootstrap’s tax-exemption policy in the 1960s, U.S. corporations could operate on the island completely exempt from all federal and local taxes and could repatriate profits tax-free to the mainland. In addition, they were exempt from federal minimum-wage requirements. Both of those conditions have since been modified. Federal minimum-wage requirements were instated on the island in 1976, and in 1996 the U.S. Congress began a ten-year phaseout of Section 936 of the Internal Revenue Code, which gave corporations credits for federal taxes paid on profits gained in Puerto Rico. Thereafter, Operation Bootstrap could only offer corporations exemption from local taxes.

Many officials saw Operation Bootstrap as transforming Puerto Rico into a showcase for what American development policy could do for Latin American countries and therefore as a model or prototype that other Latin American countries should adopt as well. Bootstrap’s
importance as a model for other countries became evident in the Cold War 1960s when nearby Cuba adopted an alternative socialist development model. Operation Bootstrap, by sticking to a capitalist strategy that relied upon private investment from the United States, directly countered the Cuban socialist strategy, which relied on state investment and sought independence from traditional American economic domination. That Teodoro Moscoso became the first director of John F. Kennedy’s (1917–1963) Alliance for Progress, which was established in 1961 in large part to counter Cuban influence, underscores Bootstrap’s importance as an early model for American development policy for Latin America.

Operation Bootstrap’s basic proposals of relying on foreign, particularly American, investment and opening up economies to free trade were components of the Caribbean Basin Initiative promoted by the Ronald Reagan (1911–2004) administration in the 1980s as an answer to the 1979 Sandinista revolution in Nicaragua and revolutionary movements in El Salvador and Guatemala. They also became basic principles of the 1994 North American Free Trade Agreement (NAFTA) and attempts to develop a free trade agreement for the Americas.

More than a half century’s experience, however, indicates that Operation Bootstrap has had mixed results for Puerto Rico. There is no question that within decades the profile of its labor force changed to approximate that of the United States and other developed countries with proportionately few workers remaining in agriculture, many more in industry, and the majority in services. There is also no question that Puerto Rico’s living conditions improved, though they are still far from being at a par with those in the United States.

But Operation Bootstrap also increased the economic dependence of Puerto Rico on the United States, undercutting development of a self-sustaining economy and economic sovereignty. One of the policy’s political consequences may well have been to undercut support for political independence, with substantial numbers of Puerto Rican voters believing that the island absolutely needed continued U.S. control for economic survival.

Operation Bootstrap never accomplished one of its promised objectives: to reduce unemployment to tolerable limits. Official unemployment figures remain much higher on the island than in the United States. Because Puerto Rico’s labor-force participation rate is comparatively low, hidden unemployment is even higher. Support for the island’s unemployed population requires significant transfer payments in the form of food stamps and other welfare aid from the United States. The seeming progress Bootstrap made in lowering official unemployment figures required exporting great numbers of the unemployed to the mainland United States.

As Bootstrap-stimulated industrial investments increased, labor-intensive agriculture declined. Because of improvements in transportation technologies, including air freight, brought on by World War II necessities, it became easier for American farmers to export their surpluses to the island, sell them at low prices, and thereby take markets away from Puerto Rican farmers.

The decline of Puerto Rican farming swelled the ranks of the already large unemployed population, and the growth of unemployment outpaced the creation of Operation Bootstrap’s new industrial jobs. A significant proportion of the unemployed then migrated to the United States in search of work. In 1940, before the advent of Operation Bootstrap, 96 percent of all Puerto Ricans lived on the island. That percentage declined steadily as Operation Bootstrap-induced industrialization and agricultural decline progressed. By 1960, it had fallen to 72 percent; by 1980 to 61 percent; and in 2004 the line was crossed with a majority of Puerto Ricans living off the island, the vast majority in the mainland United States. The architects of Operation Bootstrap believed that the island was absolutely overpopulated and actively encouraged this emigration as a safety valve to keep unemployment from being higher than it otherwise would be. For the migrants though, life in the United States has proved to be problematic. Despite having on average higher incomes and less poverty than their island counterparts, their economic conditions remain among the lowest of ethnic groups in the United States, in large part owing to considerable discrimination and ethnic and racial prejudice.

OPIUM WARS

Opium Wars is a term referring to two wars that Britain fought against imperial China in the middle of the nineteenth century, presumably over the attempts of the Chinese authorities to stop the growing influx of foreign-
produced opium. The real cause of the first Opium War (1839–1842), also called the “Anglo-Chinese War,” was Chinese resistance to Britain’s free-trade demands and practices, of which the unrestricted trade in opium was only the most controversial example. Seeking to end high Chinese import duties and other restrictions on foreign trading, the British found a pretext for war when China prohibited the importation of the drug and then confiscated a British shipment of opium.

Opium had long been used in China to treat some ailments, but in the seventeenth and the early part of the eighteenth centuries millions of Chinese from all social classes began to use it recreationally. Britain’s East India Company was shipping large quantities of Indian-grown opium to China, which it traded for Chinese tea and other local products. The imperial government was so concerned at the growing number of Chinese opium addicts that in 1799 it forbade its import trade and even decreed the death penalty for illicit trafficking in opium. Despite this legal prohibition, the opium trade continued to thrive, as private traders from Britain and other Western countries, including the United States, made huge profits from selling the extract to Chinese “opium eaters.” By the late 1830s foreign merchants were importing into China an estimated 5 million pounds of the illegal drug annually. Opium smuggling had so upset China’s balance of trade that its backward economy seemed to be on the verge of collapse. The alarmed imperial authorities made opium possession illegal in 1836 and began to close down the numerous opium parlors.

In 1839 Chinese customs officials seized a shipment of opium that British merchants were planning to market in the seaport city of Canton. In response, Britain rejected the legitimacy of China’s opium ban and threatened to use military force if the confiscated opium was not returned to its British owners. When China refused, the British navy shelled Canton and occupied the coastal areas around it, including Hong Kong. The war continued until China was forced to accept the humiliating terms of the 1842 Treaty of Nanking and compensate British merchants for their lost opium. The opium trade continued and even expanded under the generous import-license privileges that the Treaty of Nanking had granted to British merchants. This first of the so-called “unequal treaties” with China also ceded Hong Kong to Britain, opened five coastal cities, including Canton, to British rights of residence and trade, and imposed a very low tariff on British imports under the “most-favored-nation” principle. In 1844 the French and the Americans pressured China into granting them the same trading rights as the British.

The second Opium War (1856–1860) is sometimes called the “Arrow War” because the British, incensed by what they felt were clear treaty violations, used as a pretext to renew hostilities the boarding and seizure of the British ship Arrow and the arrest of its twelve crew members for opium smuggling and piracy. This time France joined the British in launching a punitive expedition inland after an initial British attack had been repelled by the Chinese. A combined Anglo-French military raid into China’s hinterland led to the signing of the 1858 Treaty of Tientsin. The Chinese imperial court refused to accept the onerous terms of this second “unequal treaty” until another joint Anglo-French expedition captured the capital Peking in 1860 and forced China’s total surrender. The Treaty of Tientsin allowed foreign embassies in Peking, a closed city at that time, opened eleven more coastal cities to foreign trading, and completely legitimized the opium trade. It also allowed westerners to travel in the Chinese interior, gave Christian missionaries the right to proselytize and hold property throughout China, and lowered even further import duties on British goods. In 1860 similarly imposed treaties were signed with France, the United States, and Russia.

The Opium Wars marked the beginning of China’s century-long subjugation and servitude to foreign powers. The defeated Chinese were forced to legalize the importation of opium, accept unfair and unbalanced terms of foreign trade, open up China’s seaports and the Yangtze River to foreign commercial penetration under the so-called “treaty port” system, and exempt westerners from China’s local laws and national jurisdiction. So severely curtailed was China’s independence in that period that the Chinese still view the Opium Wars as a national disgrace.

OPPORTUNITY COST

The opportunity cost of an economic decision is the value or benefit of the next best alternative to that decision. For example, if a community decides to use part of its budget to reduce classroom size in schools, it cannot use that same money to achieve another priority, such as improving the aesthetics of the downtown area. Meeting concerns of parents and having better educated residents has clear benefits, but the opportunity cost is a more pleasing downtown drawing in tourism or new business. In opting for the former, the town must sacrifice the latter, at least until the town budget expands and there are more resources to accomplish alternative goals.

The concept of opportunity cost is a core element in the field of economics, particularly within the marginal theory of value, where economic decisions are based on maximizing benefits subject to resource constraints. Consumers are said to “maximize utility,” choosing the combination of goods that leads to the highest amount of satisfaction possible. However, the choices are limited by the consumer's budget, and the consumer must choose a combination available within the budget constraints that exist. If the consumer wishes to see another movie, two chocolate bars must be given up. The benefit or pleasure obtained from eating the two chocolate bars is the opportunity cost of going to another movie. Similarly, workers are assumed to maximize utility, choosing a mix of income from labor and enjoyment from leisure time that best meets their individual desires, given time constraints. Firms maximize profits by selecting what to produce, how much to produce, and how to produce, subject to resource constraints.

Whole societies also face trade-offs. Existing amounts of land, labor, and other resources, as well as the current state of technology, limit how much can be produced and therefore consumed. If the society chooses to produce and consume more of one good, it must trade off some amount of another good. The opportunity cost of having more of one good is the benefit of consuming the alternative.

Opportunity costs are different from accounting costs, for which only price is considered. A student may view the cost of attending school as the monetary value of tuition and fees, but the tuition and fees are the accounting costs. The opportunity costs include the loss of income and experience of full-time employment, as well as the benefit of other items the tuition and fees could have bought. However, if the parents of the student decide to support her studies by paying her the income she would have earned in full-time employment, the forgone income is no longer an opportunity cost for the student. Instead, the parents may have sacrificed a world tour or a new boat in order to support their child, essentially assuming at least part of the opportunity costs unto themselves.

Opportunity costs include both private and social costs, but individual and collective decisions may not necessarily reflect the social costs. For example, if a firm chooses to invest in a new product line rather than expand its existing line, it is basing its decision on which choice will bring in the most profits given the costs of inputs. If manufacturing the new product results in more air pollution, social costs exist that are born by the larger community. These costs, which may include additional spending on health care and pollution mitigation, are opportunity costs of the firm’s decision, even if the firm did not consider them or pay them. The calculation of an opportunity cost is not the sum of all alternatives. If the consumer is watching more movies but eating less chocolate, the opportunity cost is only the pleasure that would have been derived from the chocolate, not the chocolate and the licorice and the popcorn, or any other choice that was not considered. Also, if something is not an option, it cannot be an opportunity cost. If the consumer wants to buy some hunting land that is not for sale, the hunting land cannot be the opportunity cost of deciding to buy a new car.

The concept of opportunity cost is frequently used in public policy debates. A favorite textbook expression of this is the “guns versus butter” debate. A society can choose more guns (i.e., more military spending), but in the context of limited resources, it must give up butter (i.e., spending on meeting human needs). During the military build-up and wars of the George W. Bush administration, many argued that the additional military spending had large opportunity costs. The money could have been used, for example, to provide health care for the uninsured, invest in greater energy efficiency, or a number of other alternatives. The opportunity cost of the spending is the benefit that could have been achieved from the most valued of these alternatives.

OPPOSITIONALITY

There is a long tradition in the social sciences of examining oppositional behavior. In particular, this work has focused on the ways adolescents act in opposition to a range of authority figures, social institutions, and expected norms of behavior. Whereas much work in psychology focuses on the individual causes and consequences of oppositionality, research in sociology and education tends to characterize oppositionality as a collective cultural response to a structural condition. Debates in these fields focus on whether, as a form of resistance, oppositional culture is productive or constraining.

In one of the classic examples from this field, Paul Willis’s *Learning to Labor* (1977) examined how “working class kids get working class jobs” and in particular, what role working-class “lads’” oppositional culture played in the process of social reproduction. Willis (1977) argued that working-class nonconformity and open opposition to the school’s achievement ideology, rules, and authority structure functioned both as a critique that reflected lads’ understanding of the limited possibility of their being upwardly mobile and simultaneously made such mobility even less likely (1977). *Learning to Labor* highlighted the central paradoxes that have been echoed in related literature in the years since: that oppositionality in various forms can be characterized as resistance and that it reflects a critique of constrained structural conditions (Giroux 1983; Macleod 1995; Weis 1990), while at the same time, youths’ oppositional behavior often contributes to the reproduction of their own subordinate racial or class status.

In a related articulation of the idea of oppositionality, Douglas Massey and Nancy Denton (1993) outline what they call a “culture of segregation” that is created by external structural conditions. They write, “An alternative status system has evolved within America’s ghettos that is defined in opposition to the basic ideals and values of American society” (Massey and Denton 1993, p. 167). Similar to Willis, oppositional culture here is a rational adaptation to social and economic conditions, albeit one that may also have dysfunctional consequences for the communities in question.

In recent years oppositionality often has been discussed in reference to the work of John Ogbu and Signithia Fordham (Ogbu 1978, 1987, 1990, 1991; Fordham and Ogbu 1986). Focused in part on explaining racial differences in academic achievement, Ogbu argued that discussions of racial minorities in U.S. schools need to differentiate the experiences of involuntary from voluntary minorities. Involuntary minorities are those who have been forcibly incorporated into the United States through colonization and slavery, whereas voluntary minorities are those who have come to the United States through immigration or other voluntary means. Voluntary minorities tend to compare their prospects in the United States to those in their country of origin and thus have positive estimations of U.S. institutions and their prospects within them. In contrast, involuntary or subordinate minorities view their status in comparison to whites, and understand that they face many social, political, and institutional barriers to success. Ogbu hypothesized that, out of their understanding of structural constraint, involuntary minorities would develop an oppositional culture, disengaging from mainstream institutions and limiting the effort they put forth to succeed in them.

Since the 1990s a number of critics have challenged the oppositional culture thesis, arguing, for example, that black students neither possess an oppositional orientation toward education nor reject school as a “white thing” (Ainsworth-Darnell and Downey 1998; Carter 2005; Horvat and O’Connor 2006; O’Connor 1997, 1999; Tyson 2002). For example, James Ainsworth-Darnell and Douglas Downey (1998) use national data to show that African American students frequently report optimistic educational expectations and demonstrate more “pro-school” attitudes than their white counterparts, and that high-achieving students are more likely to be viewed as “popular” among peers. The authors conclude that African American students do not exhibit the habits and styles that are rewarded in school primarily because they do not enjoy the same structural conditions as their white counterparts. Prudence Carter (2005), Karolyn Tyson (2002), Garvey Lundy (2003), and others have suggested that this theory has not given enough attention to the ways that social institutions construct and produce oppositionality, and thus has put too much emphasis on the need for students to change their behaviors rather than focusing on the need for real change within social institutions and social arrangements more generally. In many ways this recent work continues to highlight the key questions within the field: Does oppositionality represent an accurate critique of and resistance to fundamentally unequal social arrangements? Or is oppositionality better understood as a dysfunctional cultural adaptation? These are not merely theoretical questions, because discussions of oppositional culture are central to debates about how to address a whole range of pressing social problems. Should the focus of change efforts be on social institutions and on social inequality more generally, or on the oppositional behavior of certain groups of adolescents?

**OPOPOSITIONALITY, SCHOOLING**

Oppositional identity refers to any attitudes or behaviors intended to challenge schooling. These attitudes and behaviors range from mild opposition, such as not doing homework or becoming the class clown, to more disruptive opposition, such as defying and striking teachers or walking out of class. The most extreme form of opposition is dropping out of school. The high dropout rates and low academic achievement of racial and ethnic minority and lower-class students is often explained as a result of their adoption of an oppositional identity.

An oppositional stance to school develops because students believe that education will not lead to social mobility or because school requires behaviors that are deemed incompatible with their racial, ethnic, or class identity. Historically, racial and ethnic minority and low-income students have been subjected to discriminatory practices that deny them opportunities for social mobility through education. Knowing that schooling does not lead to social mobility shapes their attitudes toward and responses to school. Since there are scant opportunities for social mobility, they develop an oppositional stance toward school that leads to disengagement and low achievement (MacLeod 1987; Ogbu 1978; Willis 1977). Oppositional identity is a form of cultural inversion in which minority and lower-income students regard certain attitudes and behaviors as “white” or “middle class” and thus inappropriate for their group. Signithia Fordham and John Ogbu (1986) identified speaking standard English, listening to white music and white radio stations, going to the opera, getting good grades, doing volunteer work, going camping, and being on time as “white” behaviors. While subscribing to these behaviors may lead to school success, it also constitutes cultural or racial suicide because it entails the rejection of their culture in favor of white culture (McLaren 1994).

Ogbu refers to the “burden of acting white” as the price that black students pay when they assume these “white” behaviors and do well in school. Fueled by peer-group pressure, fear of being accused of disloyalty, fear of losing friends, and fear of not being accepted by whites,
black students engage in oppositional behaviors that lead to underachievement (Fordham and Ogbu 1986). High achievers run the risk of being perceived as “acting white” or as being “sellouts.” Peer chastising can include verbal taunting, ostracism, and physical aggression. To avoid peer harassment, high-achieving students must mask their accomplishments by engaging in some form of opposition, such as hiding or downplaying their grades, clowning or acting crazy, pretending to put little effort into school, or having friends who can protect them. A more socially costly alternative, and one that can lead to social isolation, is to assume a raceless persona, disassociating and disidentifying from their group (Fordham 1988).

Many scholars argue that the effects of the “burden of acting white” may be overstated (Lundy 2003; Flores-Gonzalez 2005). Many students manage to maintain a racial, ethnic, or class identity while being academically successful. Some develop dual identities that enable them to meet peer demands at school and in their neighborhood or to act differently with different peer groups (Mehan, Hubbard, and Villanueva 1994; Horvat and Lewis 2003). Others are immersed in peer networks or academic tracks that foster academic achievement. Furthermore opposition to school is not necessarily the result of peer pressure to underachieve but of structural factors that make schooling a painful and identity-threatening experience for racial and ethnic minority and low-income students (Flores-Gonzalez 2005). Discrimination ensures that these students attend highly segregated schools that are usually overcrowded, understaffed, and underfunded. There they are subjected to subtractive schooling, the practice of devaluing the students’ culture by administrators and teachers who sort, select, and reward students based on their proficiency with dominant “white and middle-class” culture (Carter 2003; Valenzuela 1999). Students who display minority culture are believed by the staff to be opposing school, which leads to their being further marginalized into the lower tracks and labeled as dumb or troubled and to their punishment (detention, suspension, expulsion) for their lack of knowledge and display of the dominant culture. Prudence Carter (2003) adds that while minority students possess and make use of both dominant and nondominant culture, they often experience difficulty enacting dominant culture. It is their inadequate display of dominant culture that is found problematic and inappropriate by teachers, leading to their negative appraisals. Furthermore one must differentiate between behaviors that are truly oppositional and are intended to challenge or resist some aspect of schooling and behaviors that may be expressions of power or triggered by other issues such as sexism or racism (Giroux 1983).

Adopting an oppositional identity almost always leads to negative consequences, such as low academic performance, grade repetition, detention, suspension, expulsion, and dropping out of school. Yet it can also protect a student’s sense of self. Michelle Fine (1991) shows that students who conform to school tend to be more depressed, less politically aware, less assertive, and more conformist than those who take on an oppositional stance. In a stratified schooling system where opportunities are structured to lead most students to failure, developing an oppositional identity may shield students from the negative effects of schooling on their sense of self and may also reinforce their sense of collective identity.

Optimal Growth

Optimal growth theory occupies a central part of modern capital theory and dynamic models of planning, macroeconomics, exhaustible resources, natural resources, development economics, finance, and dynamic games. It originated with a classic 1928 paper by the mathematician Frank Ramsey, who investigated what kind of savings policy (equal to investment) would realize the largest social welfare, defined as the sum total of utilities from current and future consumption flows. Since the choice of capital stock at any point in time can only be based upon the consumption streams the stock can yield in the future, the problem necessarily takes an open-ended form with no finite terminal date for the planning horizon.

A brief and abstract statement of the typical mathematical problem in optimal growth theory follows. Let \( t \) denote time in discrete units, \( t = 0, 1, 2 \ldots \), \( k \), the stock of goods at \( t \), and \( T \), the technology set known at \( t \), composed of pairs of vectors \((x,y)\) such that from stocks \( x \) at \( t \) it is feasible to reach the stocks \( y \) at \( t + 1 \). A function \( u: T \rightarrow \mathbb{R} \) provides the maximum utility \( u(x,y) \) that is achievable, consistent with the transition of stocks from \( x \) to \( y \). Let \( k \) denote the historically given initial stock. A path from \( k \) is an infinite sequence \( \{k^t\}_{t=0}^{\infty} \) satisfying \( k_0 = k \) and \((k_t, k_{t+1}) \in T_t \), for each \( t \geq 0 \). Loosely speaking, a path is optimal if it maximizes \( \sum_{t=0}^{\infty} u_t(k_t, k_{t+1}) \) over the set of all possible paths from \( k \).

The reduced-form model stated above, developed by David Gale (1967) and Lionel McKenzie (1968), is flexible enough to allow for changing technology and tastes with very liberal interpretations of stocks, including environmental factors, fixed resources, and unfinished goods in process, to name a few. A substantial part of the literature concentrates attention on the quasi-stationary model where technology and utility is time independent; that is, there is a set \( T \), a function \( u: T \rightarrow \mathbb{R} \), and a constant discount factor \( \delta \), where \( 0 < \delta \leq 1 \), such that \( T_T = T \) and \( u(x,y) = \delta^y u(x,y) \). A special case is the extensively studied one-sector neoclassical growth model, with one consumption cum capital good, the output of which is given by a production function \( f \), and \( T = \{(x,y): x \geq 0, 0 \leq y \leq f(x)\} \).

A utility function \( w \) is defined directly over consumption \( c = f(x) - y \); so, here, \( u_t(x,y) = w(c) \). It is noteworthy that the general reduced-form formulation may allow for direct stock effects over and above the effect of consumption on utilities and is a much richer framework.

Ramsey studied the one-sector model with time as a continuous variable and the infinite sum accordingly replaced by an integral. He obtained a remarkable rule governing the optimal savings rate at each point of time, essentially the Euler equation in the calculus of variations. Ramsey focused primarily on the undiscounted case, that is, \( \delta = 1 \); much later Tjalling Koopmans (1965) and David Cass (1965) treated the discounted case, that is, \( \delta < 1 \) thoroughly. The undiscounted case presents the problem that the welfare sum may not converge. Ramsey circumvented the problem by assuming that, due to constraints on tastes or technology, there is an upper bound on the achievable level of utility, and he sought to minimize the divergence of the utility level along paths from this bliss level. This problem received much more careful and rigorous attention later, employing variants of Carl C. von Weizsäcker’s (1965) overtaking criterion, which provides only a partial ranking over paths but can still yield a workable notion of optimality. Simultaneously, following Gale and William Brock (1970), existence of an optimal program was explored carefully in multisector models. The so-called golden rule program or optimal stationary state, where the per period utility along constant feasible programs is maximized, plays a role analogous to that of the bliss level in Ramsey.

Turnpike Theory

A 1945 paper by another mathematician, John von Neumann, on a general equilibrium model primarily stressing production, which established the existence of a balanced growth path with a maximal rate of expansion and associated present value prices at which the activities employed are profit maximizing, led to the turnpike property first explicated in 1958 by Robert Dorfman, Paul Samuelson, and Robert Solow. Several authors followed with rigorous proofs of turnpike theorems, which showed that planning paths, with long horizons and terminal stock accumulation as the goal, would tend to take advantage of the maximal rate of growth of the balanced path, the turnpike, by orienting stocks to those of the turnpike for most of the horizon.

In the context of optimal growth models, Roy Radner’s (1961) value-loss method was adapted by authors such as Gale and McKenzie (1968) to show that the optimal stationary state plays the role of the turnpike and optimal programs converge to the golden rule, albeit with some interesting qualifications when linearity is present in the model in an essential way. This convenient property is, in general, limited to the undiscounted case. José Scheinkman (1976) showed that for large discount factors the turnpike property holds; however, for small discount factors Jess Benhabib and Kazuo Nishimura (1985) showed that optimal cycles are possible. Later

Michele Boldrin and Luigi Montrucchio (1986) showed that chaotic optimal paths are possible. These papers gave rise to the literature on the possibility of nontrivial business cycles in deterministic macromodels with a representative agent carrying out the infinite horizon optimization. Also, the effect of variations in parameters, especially of the discount factor, on the optimal policy function became a topic of considerable interest following a remarkable 1992 paper by Gerhard Sorger (in this connection, see also Mitra et al. 2006).

Following Paul Romer (1986), models allowing aspects of externalities or public goods in production, which may have many equilibrium paths, gave rise to the literature of the indeterminacy problem surveyed in Nishimura and Alain Venditti (2006). Integration of turnpike theory with general equilibrium theory began with Robert Becker (1980) who, following up on Ramsey's conjecture, investigated the long-run wealth distribution that arises in a Ramsey-type general equilibrium model with several infinitely lived agents and related it to the discount factors of the agents.

DUALITY THEORY
Since Edmund Malinvaud (1953), the well-known connection between the static theory of price and efficiency went through a major evolution in the context of efficient allocation of resources in infinite horizon models. In the context of optimal growth models, McKenzie (1986) provides a transparent version of Martin Weitzman's 1973 proof of the existence of present value prices at which in each period myopic profit maximization takes place, with utility treated as an output. These are likened to familiar individual decision rules in competitive equilibrium, and the optimality conditions are usually called the competitive conditions. The distinctive feature of the infinite horizon aspect of the problem is that, in general, these need to be supplemented by a transversality condition, which requires that an appropriate limit condition be satisfied by the value of stocks, a condition that cannot be interpreted as a myopic decision rule. There has been some success at obtaining alternate price characterizations of optimal paths that require only period-by-period conditions to be verified by myopic agents; that is, the optimal path is “decentralizable” (see Majumdar 1992). Indeed, in a fairly wide class of production models satisfying a reachability condition, the competitive conditions alone characterize optimality (see Dasgupta and Mitra 1999a).

Duality theory played a significant role in grounding and extending the familiar macroeconomic concept of national product, based upon explicit welfare considerations in dynamic models. Weitzman (1976) observed that in a continuous-time framework, national income at any time along an optimal path is a proxy measure of the hypothetical level of constant consumption that, if possible to maintain forever, provides the same level of welfare found along the optimal path. While the same is not necessarily true for competitive equilibrium paths in general, in some models involving exhaustible resources, it is possible to extend such results to paths that are not necessarily optimal but satisfy the competitive equilibrium conditions only (see Dasgupta and Mitra 1999b). The interpretation of stocks in Weitzman is very general and may include exhaustible resources, environmental factors, and the like, leading to this literature developing a strong connection with the concept of “green” national income accounting. Connections with sustainable consumption paths have also been explored following Solow (1986).

Convexity is essential for the necessity side of duality theorems. Nonconvexity arises in many models, such as those with natural resources. The qualitative properties are significantly different (see Majumdar 2006). Nonconvexity is also of importance in endogenous growth models following Romer (1986).

Optimal growth allowing uncertain technology, changing technology, and so forth have been studied. With uncertainty, the possibility of ensuring long-run survival may temper optimality considerations in interesting ways (see Olson and Roy 2006). The additive-separable form of the welfare function is a severe restriction, and the literature on recursive utility functions seeks to address that (see Boyd 2006). Introducing population growth as a control variable raises interesting questions about appropriate forms of the welfare function.

An assessment is needed of the implications, the importance, and the weaknesses of the manifold developments in optimal growth theory, especially of the literature on cycles, chaos, and indeterminacy in the context of macrodynamics and business cycles, bearing in mind that the phenomenon of excess capacity does not appear in these models. An assessment is also needed of the models' practical significance for planning, bearing in mind that practical planning is expected to be finite horizon in nature and to rely on decentralized mechanisms for its implementation. This may yield more productive directions for future research.

**Optimism/Pessimism**

People differ in how they approach the world. Some individuals are optimistic and tend to be positive in their outlook and expectations for the future, whereas others are pessimistic and tend to have more negative expectations. Furthermore, these individual differences appear to be stable across time and context. The construct of optimism is in many ways rooted in folk wisdom, but scientific approaches have linked the concepts of optimism and pessimism to expectancy models of motivation. The optimism construct is therefore also grounded in decades of theory and research on motivation and on how such motivation is expressed through behavior.
One of the most recognized contemporary theories of optimism assumes expectancies to be dispositional, and refers to generalized expectancies that apply more or less across a person’s entire life span. Michael F. Scheier and Charles S. Carver developed the dispositional optimism concept in 1985, as well as one of the most popular measures used to assess optimism and pessimism, the Life Orientation Test (LOT). The LOT and its revised version, the LOT-R, contain items measuring both positive and negative expectancies (e.g., “In uncertain times, I usually expect the best” and “If something can go wrong for me, it will”). Both of these measures therefore provide the most direct assessment of optimism and pessimism as people usually understand these constructs.

Another approach to optimism, separate from the dispositional optimism approach, assumes that expectancies are based on individual interpretations of previous experiences. Often referred to as attributional or explanatory style, this approach is based on Martin E. P. Seligman’s work on learned helplessness. To account for human variation in responses to uncontrollability, the attributional reformulation of learned helplessness specifically focused on people’s explanations for events. Optimists interpret bad events as temporary, limited in scope, and not resulting from personal fault. Pessimists on the other hand, are more likely to interpret bad events as long lasting, pervasive in scope, and due to their own fault. Optimists’ tendency to attribute negative events to unstable, specific, and external causes contributes to their resiliency to negative experiences and helplessness.

Attributional style is measured with the Attributional Style Questionnaire (ASQ), which Chris Peterson and colleagues developed in 1982. The ASQ consists of six negative event items and six positive event items. For each event, the person gives one major cause for why the event occurred and rates the internality, stability, and globality of the cause. Attributional style can also be assessed through spoken or written material, using the content analysis of verbatim explanations (CAVE) method Peterson and colleagues developed in 1983. In this method, good and bad events are rated along three dimensions (internal, stable, global) using a seven-point continuum. On both of these scales, a person considering positive events to be happening due to internal, stable, and global events is considered to have an optimistic explanatory style. If a person considers negative events to be happening due to internal, stable, and global events, this individual is considered to have a pessimistic explanatory style.

Differences between optimists’ and pessimists’ attributional styles can account for different expectancies. In attributing causes to their own behavior rather than to external factors, optimists believe in their ability to influence event outcomes. On the other hand, pessimists often judge events as being caused by external factors and see no opportunity to influence the outcomes. When these attributions are stable and global, as they often are for pessimists, helplessness results.

Whereas attributional styles are generally based on interpretations of previous experiences, the construct of dispositional optimism arose from a general self-regulatory framework. Because optimists see positive outcomes as attainable, they are more likely to invest continued effort in order to achieve their goals, instead of disengaging and giving up, as pessimists might do. This tendency of optimists to expect positive outcomes and remain engaged in challenges creates a self-fulfilling prophecy in which positive outcomes and success can be actualized. For pessimists, on the other hand, the tendency to expect negative outcomes and give up on challenges creates a self-fulfilling prophecy of failure.

One of the mechanisms by which dispositional optimism and attributional style translate into better adjustment is through coping with stressors. Optimists appear to cope in active ways that help them adjust better to stressful situations. Optimists’ resilience to helplessness and effortful behaviors has been found to be positively associated with approach coping strategies aiming to eliminate, reduce, or manage stressors, and negatively associated with avoidance coping strategies aiming to avoid, ignore, or withdraw from stressors. High optimism may therefore led to approach coping, which again may lead to better adjustment to stressors.

Positive outcome expectancies and optimistic explanatory styles may also be protective factors contributing to resiliency, both psychologically and physiologically. For example, high dispositional optimism has been associated with less distress, anxiety, and depression in women with breast cancer and has been found to be protective of distress in women coping with in vitro fertilization failure. Pessimistic attributional style has also been associated with depression and distress. As for physiological well-being, dispositional optimism has been associated with a faster rate of physical recovery from coronary artery bypass surgery and has been linked to lower changes of hospitalization for cardiac patients. Dispositional optimism has also been linked to longer survival in cancer patients and to better recovery and resistance to postsurgical infection in transplant patients. Optimistic attributional style has also been positively correlated with vigorous immune reaction to an antigen challenge as well as longer survival. Clearly, the link between positive outcome expectancies and well-being is pervasive.

Carver and Scheier’s pioneering research on generalized outcome expectancies and Seligman’s groundbreaking work on learned helplessness have led to an enhanced
understanding of the significance of positive outcome expectancies. The positive psychology movement, initiated in 1998 by American Psychological Association president Seligman, emphasizes the focus in research on positive aspects of human behavior, such as dispositional optimism. The movement highlights the importance of studying not only the negative side of human experience such as disease and distress, but also recognizing the positive aspects of human behavior such as strength and virtue. Positive psychology focuses on people's satisfaction with various aspects of their lives, and considers building positive qualities as equally important to mending the worst in life. Researchers in this area address questions relating to happiness, well-being, and human potential, among others. The positive psychology movement aims to advance the understanding of how human traits can serve to buffer against not only psychological, but also physical, ailments.

OPTIMIZATION

SEE Optimizing Behavior.

OPTIMIZING BEHAVIOR

In mathematics, optimization refers to the general ideas of choosing some element of a set to maximize a function that is defined on the set. Abstractly, if one defines a function \( f \) which is typically indexed by some set of parameters \( \theta \) from some general set \( S \) to the real numbers \( \mathbb{R} \), the function \( y = f(s, \theta) \); optimization is typically nothing more than asking which element of \( S \) produces the largest value of \( y \). Notice that the set can contain complicated objects, including infinite sequences, or functions.

In economics, the notion of optimization has been used to model individual behavior. Indeed, neoclassical economic reasoning is typically predicated on the assumption that individual actors optimize in the sense that, subject to a set of constraints and beliefs about the consequences of their actions, agents choose actions that are optimal relative to their preferences. In a classic microeconomics problem, a consumer is assumed to choose a bundle of consumption goods to maximize utility subject to a budget constraint. This problem produces a relationship between relative prices and the marginal utilities of different goods. A more complicated version of this problem can ask what consumption/saving rules maximize a lifetime notion of utility in the presence of uncertainty about the future (cf. Brock and Mirman 1972). Under appropriate convexity assumptions, this type of stochastic growth model can be used to represent intertemporal general equilibrium in an economy with a representative consumer by the device of support prices constructed from the optimization problem. This approach has been fruitful in macroeconomics.

The notion that individual agents optimize is controversial from the perspectives of other social sciences. A gross simplification of this controversy is that sociologists focus much more on how social structures influence individual preferences and beliefs whereas psychologists emphasize empirically based descriptions of individual decisionmaking which can incorporate cognitive errors and limitations in the processing of information as well as what, from the perspective of the neoclassical economic theory of choice, are inconsistencies in preferences.

These alternative perspectives have become part of current economic reasoning. Herbert Simon was an early pioneer of work on bounded rationality, which emphasized limits to the ability of individuals to optimize. Simon advocated the alternative idea that individuals satisfy, that is, make acceptable rather than optimal
actions. Simon’s views did not affect most economic practice. Rather, experimental research pioneered to a great extent by psychologists Amos Tversky and Daniel Kahneman created a strong case that the standard optimization assumptions in economics were flawed for many contexts. There is a rich literature that attempts to both empirically identify (again, via experiments) and formally model individual decisionmaking that accounts for limits to human reasoning in economically interesting environments. Efforts also exist to expand the formulation of preferences to account for social context and social preferences such as altruism, although this work seems less a challenge to the notion of optimization than a reconsideration of the objectives of individuals. Together, this work is known as behavioral economics.

An alternative approach to relaxing the standard optimization paradigm is to ask whether, in dynamic environments, individual behavior will evolve toward optimality. This question, which is a major theme of evolutionary game theory, does not admit a simple answer, as different models produce different results. But interesting environments have been identified where this convergence does occur.

Perhaps the appropriate lesson is that the appropriateness of optimization assumptions depends on contexts. For example, the empirically well established absence of arbitrage opportunities in financial markets suggests in modeling individual traders, they are optimizing to the extent that for the market as a whole, all such possibilities are eliminated. Also one should not underestimate the capacity of optimization models to explain seemingly irrational behaviors, as demonstrated by the Gary Becker and Kevin Murphy (1988) model of rational addiction. Efforts to move economic models away from optimization assumptions have yielded many valuable insights, but it is hardly the case that the optimization paradigm no longer has a key role to play in economic analysis.

ORDINALITY

The concept of ordinality belongs to the broad issue of utility, preferences, and measurement of pleasure or consumer satisfaction. Economists and social philosophers have always aimed at explaining how to overcome the omnipresent scarcity that nature imposes upon humans, and thus to achieve a state of higher satisfaction. The concept of utility was developed to mean the quality that makes a commodity—through whose consumption the satisfaction can be achieved—desired. It has always been recognized that utility is a subjective matter, because the outside observer cannot know much about why and to what extent a commodity is desired, but originally it was believed (by early utility theorists such as H. H. Gossen, W. Stanley Jevons, and Léon Walras) that utility is measurable and additive—that is, that numbers can be attached to each intensity of satisfaction (cardinal utility theory) and can be summed up to get a “total utility.” In criticizing this idea, two points were made: first, that utility is nonadditive and fundamentally unmeasurable within an individual (and much less across two individuals); and second, that one actually does not even need to assume cardinality in order to make use of utility theory in economics (though cardinal utility still may exist). It came to be understood that there is an alternative approach, represented by the concept of ranking of avail-
able options that satisfy consumer preferences—ordinal utility theory. This is done in two different ways.

The first of them was based on the principle of indifference. In a standard model, the consumer maximizes her satisfaction by spending her limited budget on two goods. Any combination of the quantities of the two goods yields the same satisfaction (level of utility) to the consumer, which is why she is indifferent in her choice between these combinations. Considering all such combinations gives rise (under certain assumptions) to an “indifference curve”—a tool widely used in twentieth-century microeconomics. A set of such curves for different levels of satisfaction is an “indifference map.” Similarly, considering all combinations of the two goods that can be purchased with the same limited budget gives rise to a “budget constraint.” With these tools at hand, whether the cardinal utility exists or not is immaterial for the problem of decision making, because what matters is satisfaction ranking of all the ways in which the given budget can be spent on the two goods. Thus, when seen on a graph, the best use of the budget utility-wise is the combination of the two goods represented by the intersection of the budget constraint and the indifference curve, signifying the greatest possible satisfaction (which will typically be the one that is just “touched” by the budget constraint). This approach is associated with the work of Robert Edgeworth, Vilfredo Pareto, John Hicks, and Roy G. D. Allen, among others.

In the second approach to ordinal utility, every acting person can make a ranking of his alternative ends according to his values. This ranking, rooted in the process of subjective valuation, brings about the construction of an individual preference scale. In every action a choice is made and a part of the preference scale is demonstrated, so that the external observer can get “data” about other people’s utility ranking. For example, we can see that an individual who is buying a book ranks the $20 he is spending lower than he ranks the book on his preference scale, whereas a seller of the book has a reverse preference ranking—that is, she values the money more than the book, and therefore she is willing to sell. Value scales can be used to formulate the theory of exchange and build up a price theory and the whole of microeconomics. This approach was elaborated by Carl Menger and Eugen von Böhm-Bawerk and their followers of the so-called “Austrian school”—the Czech economist Franz Cuhel, the Austrian economists Ludwig von Mises and Friedrich Hayek, and their American followers Israel Kirzner and Murray Rothbard.

There is no doubt that utility theory is the cornerstone of the theory of consumer behavior, and yet there seems to be no general consensus on the underlining issues related to the nature of utility. On the one hand, defenders of value scales are criticized by those using indif-

ference curves that working solely with ranked units of goods hinders the use of more sophisticated mathematical analysis and model building. Users of indifference curves are criticized on the other hand because indifference cannot be demonstrated in action—that is, an actor always prefers in his action A over B, so when observing actual behavior, the “data” we see is preference, not indifference. Thus, indifference should not then be a category of economics, but of psychology. Some argue, however, that utility theory needs more psychology, to provide more input into economics because actual preference ranking may be biased or uninformed. Lastly, some authors argue, the dichotomy between ordinality and cardinality is mostly artificial and does not play any significant role when policy implications are discussed.

ORDINARY LEAST SQUARES REGRESSION

Ordinary least squares (OLS) regression is a statistical method of analysis that estimates the relationship between one or more independent variables and a dependent variable; the method estimates the relationship by minimizing the sum of the squares in the difference between the observed and predicted values of the dependent variable configured as a straight line. In this entry, OLS regression will be discussed in the context of a bivariate model, that is, a model in which there is only one independent variable (X) predicting a dependent variable (Y). However, the logic of OLS regression is easily extended to the multivariate model in which there are two or more independent variables.

Social scientists are often concerned with questions about the relationship between two variables. These include the following: Among women, is there a relationship between education and fertility? Do more-educated
Ordinary Least Squares Regression

women have fewer children, and less-educated women have more children? Among countries, is there a relationship between gross national product (GNP) and life expectancy? Do countries with higher levels of GNP have higher levels of life expectancy, and countries with lower levels of GNP, lower levels of life expectancy? Among countries, is there a positive relationship between employment opportunities and net migration? Among people, is there a relationship between age and values of baseline systolic blood pressure? (Lewis-Beck 1980; Vittinghoff et al. 2005).

As Michael Lewis-Beck notes, these examples are specific instances of the common query, “What is the relationship between variable X and variable Y?” (1980, p. 9).

If the relationship is assumed to be linear, bivariate regression may be used to address this issue by fitting a straight line to a scatterplot of observations on variable X and variable Y. The simplest statement of such a relationship between an independent variable, labeled X, and a dependent variable, labeled Y, may be expressed as a straight line in this formula:

\[ Y = a + bX + e \]  

where \( a \) is the intercept and indicates where the straight line intersects the Y-axis (the vertical axis); \( b \) is the slope and indicates the degree of steepness of the straight line; and \( e \) represents the error.

The error term indicates that the relationship predicted in the equation is not perfect. That is, the straight line does not perfectly predict \( Y \). This lack of a perfect prediction is common in the social sciences. For instance, in terms of the education and fertility relationship mentioned above, we would not expect all women with exactly sixteen years of education to have exactly one child, and women with exactly four years of education to have exactly eight children. But we would expect that a woman with a lot of education would have fewer children than a woman with a little education. Stated in another way, the number of children born to a woman is likely to be a linear function of her education, plus some error. Actually, in low-fertility societies, Poisson and negative binomial regression methods are preferred over ordinary least squares regression methods for the prediction of fertility (Poston 2002; Poston and McKibben 2003).

We first introduce a note about the notation used in this entry. In the social sciences we almost always undertake research with samples drawn from larger populations, say, a 1 percent random sample of the U.S. population. Greek letters like \( \alpha \) and \( \beta \) are used to denote the parameters (i.e., the intercept and slope values) representing the relationship between \( X \) and \( Y \) in the larger population, whereas lowercase Roman letters like \( a \) and \( b \) will be used to denote the parameters in the sample.

When postulating relationships in the social sciences, linearity is often assumed, but this may not be always the case. Indeed, a lot of relationships are not linear. When one hypothesizes the form of a relationship between two variables, one needs to be guided both by the theory being used, as well as by an inspection of the data.

But given that we wish to use a straight line for relating variable \( Y \), the dependent variable, with variable \( X \), the independent variable, there is a question about which line to use. In any scatterplot of observations of \( X \) and \( Y \) values (see Figure 1), there would be an infinite number of straight lines that might be used to represent the relationship. Which line is the best line?

The chosen straight line needs to be the one that minimizes the amount of error between the predicted values of \( Y \) and the actual values of \( Y \). Specifically, for each of the \( i \)th observations in the sample, if one were to square the difference between the observed and predicted values of \( Y \), and then sum these squared differences, the best line would have the lowest sum of squared errors (SSE), represented as follows:

\[ \text{SSE} = \sum (\hat{Y} - \bar{Y})^2 \]  

Ordinary least squares regression is a statistical method that produces the one straight line that minimizes the total squared error.

Using the calculus, it may be shown that SSE is the lowest or the “least” amount when the coefficients \( a \) and \( b \) are calculated with these formulas (Hamilton 1992, p. 33):

\[ b = \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sum (X - \bar{X})^2} \]  

\[ a = \bar{Y} - b \bar{X} \]

These values of \( a \) and \( b \) are known as least squares coefficients, or sometimes as ordinary least squares coefficients or OLS coefficients.

We now will apply the least squares principles. We are interested in the extent to which there is a relationship among the counties of China between the fertility rate (the dependent variable) and the level of illiteracy (the independent variable). China had 2,372 counties in 1982. We hypothesize that counties with populations that are heavily illiterate will have higher fertility rates than those with populations with low levels of illiteracy.

The dependent variable, \( Y \), is the general fertility rate, GFR, that is, the number of children born in 1982 per 1,000 women in the age group fifteen to forty-nine. The independent variable, \( X \), is the percentage of the population in the county in 1981 aged twelve or more who are illiterate.
The relationship may be graphed in the scatterplot in Figure 1. The association between the GFR and the illiteracy rate appears to be linear and positive. Each dot refers to a county of China; there are 2,372 dots on the scatterplot.

Equation (1) may be estimated using the least squares formulas for \( a \) and \( b \) in equations (3) and (4). This produces the following:

\[
\hat{Y} = 57.56 + 1.19x \tag{5}
\]

The OLS results in equation (5) indicate that the intercept value is 57.56, and the slope value is 1.19. The intercept, or \( a \), indicates the point where the regression line “intercepts” the \( Y \)-axis. It tells the average value of \( Y \) when \( X = 0 \). Thus, in this China dataset, the value of \( a \) indicates that a county with no illiterate person in the population would have an expected fertility rate of 57.6 children per 1,000 women aged fifteen to forty-nine.

The slope coefficient, or \( b \), indicates the average change in \( Y \) associated with a one-unit change in \( X \). In the China example, \( b = 1.19 \), meaning that a 1 percent increase in a county’s illiteracy rate is associated with an average GFR increase, or gain, of 1.19 children per 1,000 women aged fifteen to forty-nine.

We would probably want to interpret this \( b \) coefficient in the other direction; that is, it makes more sense to say that if we reduce the county’s illiteracy rate by 1 percent, this would result in an average reduction of 1.2 children per 1,000 women aged fifteen to forty-nine. This kind of interpretation would be consistent with a policy intervention that a government might wish to use; that is, a lower illiteracy rate would tend to result in a lower fertility rate.

The regression line may be plotted in the above scatterplot, as shown in Figure 2.

It is noted that while in general the relationship between illiteracy and fertility is linear, there is a lot of error in the prediction of county fertility with knowledge of county illiteracy. Whereas some counties lie right on or close to the regression line, and therefore, their illiteracy rates perfectly or near perfectly predict their fertility rates, the predictions for other counties are not as good.

One way to appraise the overall predictive efficiency of the OLS model is to “eyeball” the relationship as we have done above. How well does the above OLS equation correspond with variation in the fertility rates of the counties? As we noted above, the relationship appears to be positive and linear. A more accurate statistical approach to address the
question of how well the data points fit the regression line is with the coefficient of determination ($R^2$).

We start by considering the problem of predicting $Y$, the fertility rate, when we have no other knowledge about the observations (the counties). That is, if we only know the values of $Y$ for the observations, then the best prediction of $Y$, the fertility rate, is the mean of $Y$. It is believed that Carl Friedrich Gauss (1777–1855) was the first to demonstrate that lacking any other information about a variable’s value for any one subject, the arithmetic mean is the most probable value (Gauss [1809] 2004, p. 244).

But if we guess the mean of $Y$ for every case, we will have lots of poor predictions and lots of error. When we have information about the values of $X$, predictive efficiency may be improved, as long as $X$ has a relationship with $Y$. “The question then is, how much does this knowledge of $X$ improve our prediction of $Y$?” (Lewis-Beck 1980, p. 20).

First, consider the sum of the squared differences of each observation’s value on $Y$ from the mean of $Y$. This is the total sum of squares (TSS) and represents the total amount of statistical variation in $Y$, the dependent variable.

Values on $X$ are then introduced for all the observations (the Chinese counties), and the OLS regression equation is estimated. The regression line is plotted (as in the scatterplot in Figure 2), and the actual values of $Y$ for all the observations are compared to their predicted values of $Y$. The sum of the squared differences between the predicted values of $Y$ and the mean of $Y$ is the explained sum of squares (ESS), sometimes referred to as the model sum of squares. This represents the amount of the total variation in $Y$ that is accounted for by $X$. The difference between TSS and ESS is the amount of the variation in $Y$ that is not explained by $X$, known as the residual sum of squares (RSS).

The coefficient of determination ($R^2$) is:

$$R^2 = \frac{\text{ESS}}{\text{TSS}}$$

The coefficient of determination, when multiplied by 100, represents the percentage amount of variation in $Y$ (the fertility rates of the Chinese counties) that is accounted for by $X$ (the illiteracy rates of the counties). The $R^2$ values range from +1 to 0. If $R^2 = 1.0$, the $X$ variable perfectly accounts for variation in $Y$. Alternately, when $R^2 = 0$ (in this case the slope of the line, $b$, would also equal 0), the $X$ variable does not account for any of the variation in $Y$ (Vittinghoff et al. 2005, p. 44; Lewis-Beck 1980, pp. 21–22).

**ORGANIZATION MAN**

This concept was made famous in mid-1950s America with the publication of William Hollingsworth Whyte's *The Organization Man* (1956). Sponsored by *Fortune Magazine* to do extensive interviews with chief executive officers of major companies such as General Electric, Whyte (1917–1999) studied white-collar employees of large, successful corporations in the heyday of the Eisenhower administration. These men did not simply work for the corporate world; they belonged to the Organization. This new stratum of American society was no longer driven by the spirit of individualism that had characterized the early Protestant settlers, the frontier, and nineteenth-century capitalism. A code was emerging that Whyte called the "social ethic," which involved a new, all-embracing fealty to the corporation. This ethic, which was associated with the growing professionalization of management and a commitment to practical expertise rather than abstract knowledge, emphasized belief in the social group as the fountain of creativity and the importance of "belongingness" for the individual. Whyte's ethnographic study was a bestseller intended for a nonacademic audience, but it had a serious purpose, which was to argue that the Protestant ethic—the ascetic individualism and sense of calling made famous by the German sociologist Max Weber—was in decline and America was changing profoundly as a result.

Weber, who visited the United States in 1904, recognized a connection between the ascetic sects of American frontier society and the European Reformation, a comparison he outlined in 1905 in *The Protestant Ethic and the Spirit of Capitalism*. Weber was impressed by the vibrant nature of local religious communities and the obvious connections between American capitalism and the asceticism and individualism of the sects. In contrast to the culture that Weber had observed, the new corporate culture, Whyte argued, did not reward thrift, hard work, and self-reliance. The organization man spent his working day in a committee and was rewarded as an administrator for working "through others for others" (p. 22). The principal influence over corporate culture was not Protestantism, but the pragmatism of John Dewey (1859–1952). Whyte's analysis formed an important social critique of corporate America, and suggested that the prospects for an energetic entrepreneurial culture were significantly diminished by the social conformism of corporate executives and their managers.

The social ethic of organization men, Whyte claimed, spilled over into their private lives. Personal saving had lost its moral imperative, and young couples in the new corporate culture saved for specific items—houses, cars, or schooling—that would give their lives more security and stability. The organization culture of 1950s suburbia created what came to be called a "lifestyle," in which couples progressed from a two-bedroom court apartment to a three-bedroom house, and subsequently to a ranch house, a split-level home, and finally, as retirement approached, back into a two-bedroom apartment. These suburbanites chose their friends from a limited social milieu, principally consisting of their suburban neighbors. Church attendance and the education of their children was key to achieving stability and security in lives that were characterized by transience, due to frequent postings to new branches of an organization. The conformist values of the organization also had implications for gender relations. Company wives were expected to be pretty but not sexy, and ambitious, but not too overtly materialistic. Even women's physical appearance expressed corporate values, which put a premium on female slenderness: As their husband's income went up, women's waistlines went down.

---
Whyte's ethnography now looks socially obsolete. Organizations at the beginning of the twenty-first century offer not life-long employment but short-term project-based careers, and company downsizing has produced a survival-oriented mentality among employees. Whyte's picture of the happy wives of organization men carefully managing their suburban households is also historically dated. The stability of life-long commitment to the company has collapsed in the face of intense economic competition in a global economy.

ORGANIZATION OF AFRICAN UNITY (OAU)
The Organization of African Unity (OAU) was postcolonial Africa's first continent-wide association of independent states. Founded by thirty-two countries on May 25, 1963, and based in Addis Ababa, Ethiopia, it became operational on September 13, 1963, when the OAU Charter, its basic constitutional document, entered into force. The OAU's membership eventually encompassed all of Africa's fifty-three states, with the exception of Morocco, which withdrew in 1984 to protest the admission of the Saharan Arab Democratic Republic, or Western Sahara. The OAU was dissolved in 2002, when it was replaced by the African Union.

The process of decolonization in Africa that commenced in the 1950s witnessed the birth of many new states. Inspired in part by the philosophy of Pan-Africanism, the states of Africa sought through a political collective a means of preserving and consolidating their independence and pursuing the ideals of African unity. However, two rival camps emerged with opposing views about how these goals could best be achieved. The Casablanca Group, led by President Kwame Nkrumah (1909–1972) of Ghana, backed radical calls for political integration and the creation of a supranational body. The moderate Monrovia Group, led by Emperor Haile Selassie (1892–1975) of Ethiopia, advocated a loose association of sovereign states that allowed for political cooperation at the intergovernmental level. The latter view prevailed.

The OAU was therefore based on the “sovereign equality of all Member States,” as stated in its charter.

AIMS AND OBJECTIVES
Article 2 of the OAU Charter stated that the organization's purposes included the promotion of the unity and solidarity of African states; defense of their sovereignty, territorial integrity, and independence; and the eradication of all forms of colonialism from Africa. Member states were to coordinate and harmonize their policies in various areas, including politics and diplomacy, economics, transportation, communications, education, health, and defense and security. Article 3 of the OAU Charter included among its guiding principles the sovereign equality of all member states, noninterference in the internal affairs of states, respect for sovereignty and territorial integrity, the peaceful settlement of disputes, and the emancipation of dependent African territories. Although the organization's primary motivation initially was the liberation struggle and the defense of the independence and territorial integrity of African states, the OAU later expanded its scope of activities to encompass economic cooperation and the protection of human rights.

PRINCIPAL INSTITUTIONS
The OAU’s Assembly of Heads of State and Government was the organization’s supreme organ. It normally met once a year, in a different capital city, although it could also meet in extraordinary session. Although each state had one vote, the assembly tended to operate by consensus. Except for internal matters, its resolutions were nonbinding.

The Council of Ministers, composed of government ministers (usually foreign ministers), normally met twice a year or in special session. Subordinate to the Assembly of Heads of State and Government, the council’s principal responsibility was preparing the assembly’s agenda. The council implemented the assembly’s decisions and adopted the budget. In practice it emerged as the OAU’s driving force.

The General Secretariat was headed by a secretary-general, appointed by the Assembly of Heads of State and Government. The secretariat was responsible for the administration of the OAU. The secretary-general was initially envisaged as an apolitical administrator, but over time the office assumed a proactive role, including acquiring the power under the Mechanism for Conflict Prevention to resolve disputes. The General Secretariat became mired in controversy in 1982 when the decision was taken to admit the Saharan Arab Democratic Republic to the organization. Morocco challenged the legality of this decision as it claimed that the Saharan Arab Democratic Republic was not a state. Since 1975 Morocco had occupied most of Western Sahara, a former
Spanish colony, and was engaged in a war against the Polisario Front, which had declared the Saharan Arab Democratic Republic an independent state in 1976 and was fighting for its liberation. The United Nations is still trying to settle this dispute.

The Commission of Mediation, Conciliation, and Arbitration, established as the OAU’s dispute settlement mechanism, had jurisdiction over disputes between member states only. Member states, the Assembly of Heads of State and Government, and the Council of Ministers could refer disputes to the commission, but only with the prior consent of the states concerned. The commission never became operational because African governments were distrustful of third-party adjudication.

ADDITIONAL INSTITUTIONS
The African Commission on Human and Peoples’ Rights, established under the African Charter on Human and Peoples’ Rights (1982), became operational in 1987. Based in Banjul, Gambia, and composed of eleven individuals, the commission is a treaty monitoring body with the specific mandate of promoting and protecting human and peoples’ rights. Particularly important is its competence to hear complaints from individuals and nongovernmental organizations concerning alleged violations by parties to the Charter on Human and Peoples’ Rights. After an uncertain beginning, the commission is becoming a more effective defender of human and peoples’ rights. The commission now functions under the auspices of the African Union and shares responsibility for the protection of human rights with the African Court on Human and Peoples’ Rights.

The African Court on Human and Peoples’ rights was established under a protocol to the Charter on Human and Peoples’ Rights in 1998 that came into force in 2004. The court’s jurisdiction over human rights treaties is broad in scope. The Commission, African Intergovernmental Organizations, and participating states can submit cases to the Court, as can individuals and nongovernmental organizations with the permission of the accused state. Its judgments are binding, but it can also give advisory opinions.

The Mechanism for Conflict Prevention, Management, and Resolution was founded in 1993 with the task of finding political solutions to disputes between OAU member states. Its primary objective was the anticipation and prevention of conflicts, with emphasis on the adoption of anticipatory and preventative measures, especially confidence-building measures. The mechanism operated subject to the fundamental principles of the OAU, especially with regard to the sovereignty and territorial integrity of member states and the principle of non-interference in their internal affairs. The mechanism’s role was therefore subject to the consent and cooperation of the warring parties. The mechanism was able to mediate in various civil conflicts and participate in election monitoring, but it never acquired the capacity to provide peacekeeping forces.

EVALUATION
The OAU had a mixed record. Its greatest success was in relation to decolonization. Other achievements included making significant contributions to the development of international law, especially in the fields of refugee law and human rights law, where several important treaties were adopted under OAU auspices, although in practice progress was slow and uneven. A court of human rights was envisaged, but the OAU was dissolved before it was established. Efforts were made to promote economic cooperation, and in 1991 it was decided to set up an African economic community, which in time was intended to lead to a customs union, a common market, and African monetary union. Little progress was made.

Overall, the failures of the OAU outweighed its successes. Arguably, its major failing was its inability to bring peace, prosperity, security, and stability to Africa. The OAU was found wanting in its responses to the tyrannies and kleptocracies ruining Africa, a deficiency that undermined its credibility. Its powers were too weak and its influence inadequate to deal with the internal and external conflicts, poor governance, human rights abuses, poverty, and underdevelopment from which much of Africa suffered. The OAU was also considered incapable of meeting the challenges of globalization. By the end of the century, reform so comprehensive was required that it was decided to start afresh with a new organization, the African Union, devoted to the political and economic integration of Africa based on respect for democratic values, good governance, the rule of law, and human rights.

Throughout its history, the Organization of Petroleum Exporting Countries (OPEC) has indirectly influenced oil prices in response to sharp volume fluctuations resulting from geopolitical tensions. However, as of 2006 OPEC’s effect on the market, which affords member states political leverage, has changed dramatically relative to the late twentieth century, because member states now have far less excess production capacity (see Figure 1).

OPEC had more excess oil capacity in the 1980s, when crude oil prices reached close to $80 a barrel, than it did by 2006, during which prices reached as high as $75 a barrel (Figure 2). Minimal surplus capacity limits OPEC’s ability to soften the blow of the high price of oil via increasing supply to meet the immense demand.

The Organization consists of eleven developing nations whose economies rely heavily on oil export revenues. OPEC seeks to maintain stable international oil prices via quotas on oil production and pursue petroleum policies that serve the national and collective interests of its members. In 2002 OPEC agreed that a fair price on crude oil should be set between $22 and $28 a barrel. Three years later, member states agreed to cap their crude oil production at 28 million barrels per day (MBPD). By 2006 Qatari Energy Minister Abdullah Attiyah maintained that a fair market price for crude oil should be in the range of $50 to $55 a barrel. However, during the

**Source:** Kochhar, Ouliaris, and Samiei 2005, 2.
same year, crude oil prices reached over $70 a barrel, and some OPEC countries often surpassed their production quotas by 2 MBPD.

Prior to OPEC, the so-called Seven Sister Companies dominated the crude oil market. Those seven companies included Esso (which later became Exxon, and is now known as Exxon Mobil), the Anglo-Iranian (previously Anglo-Persian) Oil Company (later British Petroleum, and currently known as BP), Royal Dutch Shell, Gulf Oil (most of which became a part of what is today known as Chevron), Standard Oil of New York (which became Mobil, and later merged with Exxon), Texaco, and Standard Oil of California (now part of Chevron) (see Table 1). Crude oil prices remained stable, with a range from $2.50 to $3.00 a barrel during the late 1940s through the 1960s, or $21 to $22 a barrel when adjusted to 2006 dollars.

The Seven Sister Companies remained dominant by restricting oil output and minimizing internal conflict. But competition from other world suppliers would eventually break up their control over the international oil market.

OPEC was created at the Baghdad Conference on September 10–14, 1960, by Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela. Eight more countries later joined the Organization—Qatar (1961), Indonesia (1962), Libya (1962), United Arab Emirates (1967), Algeria (1969), Nigeria (1971), Ecuador (1973), and Gabon (1975). OPEC set up a secretariat in Geneva, Switzerland, which moved to Vienna in 1965. The OPEC Statute states that countries that apply for membership must maintain “a substantial net export of crude petroleum” and “have fundamentally similar interests to those of Member Countries” (OPEC Statute, p. 3). The formation of OPEC resulted in a shift in influence over the oil market away from the Seven Sister Companies toward OPEC.

OPEC’s dominance became fully evident during the 1970s as its Arab member states limited oil shipments and cut production at a time when demand was high, which resulted in a spike in oil prices. The Arab countries imposed an embargo on oil shipments to the United States

### Table 1
and any other country that condemned Egypt and Syria’s attack on Israel in 1973, which was significant considering that OPEC exports accounted for 85 percent of world oil trade at the time (Mikdashi 1974, p. 4). According to data from the *Middle East Quarterly* and *WTRG Economics*, the nominal price of oil escalated by more than 300 percent at the end of 1974 compared to prices a decade earlier. OPEC validated its authority and gained political leverage by reducing oil supply to the world market.

During this same period, Libya became a more prominent member of OPEC. Libya had undergone a regime change a few years earlier as the result of a military coup led by Colonel Muammar al Qadhafi, and had officially become known as the Great Socialist People’s Libyan Arab Jamahiriya. Qadhafi encouraged Arab-nationalist and socialist policies. Many analysts have credited the new Libyan regime with shaping OPEC’s measures to increase oil prices, enforce embargoes, and gain control of oil production (Anderson 1999, p. 4). For example, according to a 1973 *Time Magazine* article, Qadhafi took advantage of the high global demand for oil by forcing oil companies to increase Libya’s oil royalties over 100 percent from $1.1 billion in 1969 to $2.07 billion in 1971 (“The Arab World,” p. 2). Libya’s influence played a partial role in OPEC’s enhanced political strength on the world stage.

OPEC’s reaction to the scarcity of oil supply resulting from the Iranian Revolution in 1979 and the Iraqi invasion of Iran in 1980 further illustrated its strength. The new regime in Iran, which was the second largest OPEC oil exporter following Saudi Arabia, curbed oil exports to the world market driving prices upward. By 1979 Iran produced less than 1 MBPD, which was down from over 6 MBPD a year earlier (“Iran and Oil Prices,” *Washington Times*, January 17, 2006; Phillips 1979, pp. 1–2). Iraq’s invasion of Iran in 1980 sparked a reduction in the combined production of both countries to only 1 MBPD and a jump in prices from about $14 per barrel by early 1979 ($43.48 in 2006 dollars), to $35 per barrel by 1981 ($77.97 in 2006 dollars), according to *WTRG Economics*. Other countries within OPEC were able to offset Iran and Iraq’s lower oil production by increasing their output while also maintaining a substantial amount of excess capacity. Saudi Arabia alone utilized three-quarters of its production capacity in order to make up for reduced output. Additional output from the other OPEC members helped crude oil prices to fall.

However, increased OPEC crude oil supply resulted in an oil price collapse by the mid-1980s. A Brookings Institution report entitled “Lessons from the 1986 Oil Collapse” (1986) notes that Saudi Arabia increased its market share after many of its OPEC partners failed to abide by their production quotas, thus oversupplying the market. Consequently, in 1986 crude oil prices declined from over $20 to as low as $12 a barrel ($22.17 in 2006 dollars).

![Proven oil reserves 1991—OPEC, Saudi Arabia vs. non-OPEC](source: Lieber 1992, 161.)
Lack of cohesion among member states presented a challenge to the effectiveness of OPEC during this period.

By the early 1990s, the price of oil began to creep upward with the Iraqi invasion of Kuwait and the resultant threat of a Persian Gulf war. Saudi Arabia possessed the most oil reserves regionally and internationally (see Figure 3).

Saudi Arabia increased production by more than 3 MBPD during the Gulf War of 1991 (Lieber 1992, p. 155). This increased output to offset shortages created by the Gulf War of 1991 resulted in the stabilization of prices shortly after.

As the twenty-first century began, many geopolitical tensions further limited OPEC’s oil supply and raised prices. The 2002 strike by state-owned Petroleos de Venezuela caused Venezuelan oil production to plunge so low that Venezuela still has not been able to regain its peak output capacity of 3.5 MBPD. In addition, the international military action in Iraq in 2003 caused Iraqi output to plummet to less than 1.5 MBPD. In 2006 Iran’s threat to slash oil exports during its dispute with the United Nations over its nuclear missile program kept oil prices high at over $70 a barrel.

OPEC’s ability to offset price increases in the early part of the twenty-first century pales in comparison to its clout during political conflicts thirty years earlier because there is far less additional oil supply in OPEC countries, including Saudi Arabia. The U.S. Energy Information Administration reported Saudi Arabia’s excess capacity as being around 1.3 to 1.8 MBPD in May of 2006. Other OPEC members have zero surplus capacity in a world that consumes around 80 MBPD (see Figure 4). By the first half of 2006, oil prices jumped from $50 a barrel to a little more than $70 a barrel. Although the price per barrel is a few dollars shy of that in 1981 ($77.97 in 2006 dollars), the peak production capacity of OPEC is far less than that of the early 1980s, thus reducing OPEC’s ability to manipulate the market.

OPEC’s impact on the international crude oil market will continue to wane with such a tight supply. High crude oil prices have led to discussions about the possibility of tapping new oil reserves in non-OPEC countries and expanding alternative sources of energy, such as ethanol, in order to meet high demand at a much lower cost.

Organization Theory

BIBLIOGRAPHY

ORGANIZATION THEORY

Organization theory is a theoretical perspective which conceives of organizations as complex social actors and investigates how the structures they adopt affect their behavior. The field takes a broad view of the term “structure” including not only formal structure, but also informal and network relationships and cultural and cognitive aspects of the organizations. As such, it addresses broad questions of how and why organizations come to be, take the forms they do, behave as they do, and survive or fail. With its focus on organizations as a collective entity, organization theory complements organizational behavior, which focuses on individuals and small groups within the larger field of organization studies.

BACKGROUND AND ORIGINS

Organization theory was derived from several fields, including sociology, economics, anthropology, and political science. Many scholars in these fields have influenced organization theory, including Émile Durkheim, Karl Marx, Adam Smith, and Max Weber. Of these, Weber most directly influenced organization theory with his work on authority and bureaucracy.

Writing around the turn of the twentieth century, Weber identified two sources of authority that dominated previous social organization: traditional authority, vested in established patterns of behavior passed down through generations, and charismatic authority, vested in an individual’s powers of attraction and influence over others. He also identified a third form, rational-legal authority, in which authority is vested in individuals selected based on rules and legally binding processes designed to identify those best qualified to exercise it. This rational-legal authority is the basis of Weber’s theory of bureaucracy, in which he posited that organizing in this manner could generate remarkable social advances comparable in magnitude to the economic advances of the Industrial Revolution. Furthermore, Weber’s ideal view of rationality comprised two types: substantive rationality, which determines what a social group’s goals, values, and ideals should be, and formal rationality, which governs how a social group allocates resources and measures progress toward those goals and ideals. In an oft-quoted passage he warned that formal rationality without substantive rationality could lead to a dehumanizing “iron cage.” While some critics suggest that early English translations of Weber did not sufficiently reflect the true spirit of his work, Weber has nevertheless provided a foundation upon which much of organization theory has been built.

Building on Weber and others, more recent organization theorists have generally emphasized two primary per-
spectives on the nature and function of organizations, which have been elaborated into a number of influential theories of organizations. The first of these perspectives considers organizations as rational and efficient solutions to various problems associated with cooperation, complexity, and uncertainty. The second perspective considers organization not on the basis of its rational structure and function but rather on the basis of its social meaning and value.

ORGANIZATIONS AS RATIONAL SOLUTIONS TO SOCIAL PROBLEMS

Some of the earliest theories of organizations emerged in the wake of the Industrial Revolution and were characterized by the search for universal organizing principles. Influential among these early theorists were Frederick Taylor and Henri Fayol, whose work can be characterized as the application of mechanical and industrial engineering principles to the management and control of human labor. However, in the 1960s organization theorists turned attention from universal organizing principles to theories that argued that ideal organization structures were not one-size-fits-all, but instead contingent on various factors within the organization and its environment.

In 1967, Paul Lawrence and Jay Lorsch introduced contingency theory, which claimed that the best way to organize depends upon the characteristics of an organization's environment. Lawrence and Lorsch argued that organizations' environments vary widely and that organizations come to reflect this variety by rationally adopting structures best suited to their environments. They showed that the degree of volatility and uncertainty in an organization's environment affects things like the formalization of an organization's structure, the centrality of its decision making, the time horizon upon which it focuses, and how it divides itself into departments and its tasks. Lawrence and Lorsch's emphasis on contingencies proved influential, and several other contingency-based theories of organizations emerged in the 1970s. Among these are agency theory, transaction cost economics, and resource dependence theory.

Agency theory focuses on the fact that, in organizations, one person (the agent) acts at the behest of another (the principal). This principal–agent relationship exists in organizations between stockholders and managers and between managers and employees. Agency theorists assume that both agents and principals have self-interests and that these interests frequently diverge. This creates a need for principals to monitor the agents, which is difficult and expensive since agents often have more expertise than principals and cannot be continuously and directly observed. Agency theorists therefore depict organizational structures as rational attempts to establish complex yet efficient systems of cooperation, which differ from organization to organization and task to task depending on the information asymmetry between principals and agents.

Transaction cost economics (TCE) is closely related to agency theory, but instead of emphasizing how organization structures govern internal principal–agent relationships, TCE emphasizes that organizations are rational and efficient solutions to managing the relationship between itself and other organizations in its environment. Oliver Williamson, who introduced TCE in the mid-1970s, argues that small-scale transactions (i.e., simple and immediate exchanges of goods and services) do not require organizations; however, as transactions become more complex and uncertain, organizations are needed to monitor and limit the liabilities of these risks. TCE also explains organizational boundaries on the basis of transaction costs: Functions for which the costs of external transactions are too great are brought inside the organization, while those available for less total cost elsewhere are performed externally.

The resource dependence view of organizations, like TCE, emphasizes an organization's relationship to other organizations but focuses on how an organization's structures are contingent on the nature and scarcity of the resources it needs to operate rather than on the complexity and uncertainty of its transactions. More so than the other contingency-based theories, the resource dependence view emphasizes the role of management in negotiating the dependencies resulting from an organization's resource needs, and specifies a number of strategies that firms may undertake to do this under different dependency conditions.

The rational/efficient assumptions within contingency-based theories of organizations also underlie the theories of population ecology and co-evolution, which conceptualize the environment shared by organizations in the same or related fields as an ecosystem. These theorists employ ecological and evolutionary mechanisms, (e.g., variation, selection, specialization) to explain how organizations come to be and survive or fail. In this stream of research, organizational success, failure, and form are contingent upon environmental adaptation, fit, and population density.

ORGANIZATIONS AS EMBODIMENTS OF VALUE AND MEANING

Another approach to addressing the questions of how organizations come into being and why they take the forms they do is based on the conception of organizations as embodiments of value and meaning. Many of these theories can be traced to Peter Berger and Thomas Luckmann's *The Social Construction of Reality* (1966), in which they suggest that, in the context of social science,
“knowledge” and “reality” are subjectively created rather than objectively discovered. Theories based on this approach shift their emphasis from identifying efficient ways of organizing to understanding the purpose or meaning derived from organizing a particular way. The shift was essentially a move from Weber’s formal rationality to substantive rationality, which critics held had been slighted by modernist social science and its natural preference for formal rationality.

One example of this branch of organization theory comes under the generic heading of institutional theory, which grows out of the concept of social institutions. While diverse definitions of institutions abound, reflecting the evolution and variety of theories under this rubric, common to all of them is the idea of stable patterns of social interaction that over time become vested with value and power. Within organization theory, institutions were first associated with the processes by which leaders infuse organizational structures or processes with value beyond their technical requirements, resulting in their reproduction and stability. In this stream of research, sometimes termed old institutionalism, the focus is on creating meaning and infusing values from within the organization.

This is contrasted with neo-institutional theory, or new institutionalism, which focuses on how external aspects of the context in which organizations exist affect their structures and processes. In a seminal piece from 1983, Paul DiMaggio and Walter Powell suggested the similarity among organizations in a field was the result of their common environment, which comprised three distinct forces for conformity: coercive forces, such as a common regulatory environment; normative forces, such as professionalization and standardized professional education (e.g., accounting); and mimetic forces, in which organizations copy visible or successful others when facing uncertainty. The idea that processes and structures result from passively adapting to external pressures contrasted directly with old institutionalism, which theorized they were actively infused with value from within. Later, in response to criticisms that neo-institutional conceptions of organizations were too passive and static, neo-institutionalists highlighted institutional change, where organizations dynamically adapt to changing institutional environments, and institutional entrepreneurship, where actors actively shape the institutional environments in which they exist. These advances, along with the concept of institutional work, have blurred the distinctions between old and new institutionalism.

These blurred distinctions are also evident in organizational culture and organizational identity, both of which focus on how organizations enact meaning within their social contexts. Organizational identity theorists address the issues of “who we are” as an organization and show a similar focus on the reproduced social meaning (i.e., what is enduring, central, and distinctive) within an organization, and how that affects the structures and processes of organizations. Work on organizational culture focuses directly on the meaning systems of organizations at three levels: artifacts, the rituals and symbols employed in an organization; values, the conscious beliefs about what should or should not be; and assumptions, the deeply held and often unconscious beliefs that guide how members make sense of an organization. Consistent with the work on the social construction of reality, this suggests that organizational action flows from values about what should or should not be, but is constrained by assumptions about what is or can be.

ORGANIZATIONS

Formal organizations are ubiquitous in modern society. Most people work in organizations, join organizations, and interact with organizations in their daily lives. The study of organizations includes an examination of the relationship between individuals and organizations, organizations and their external environments, and how corporations and other constellations of organizations exercise power and influence public policy.

INDIVIDUALS IN ORGANIZATIONS: CONTROL OVER DECISION MAKING

Organizational theorists maintain that the emergence of modern large-scale bureaucracy is an outcome of the increased application of formally rational means (e.g., written laws, rules, and regulations) to achieve the substantively rational goals (i.e., large-scale capitalism, democracy) associated with modernity. Although large-scale organizations can be used to increase the productive capability of capitalism and extend democracy to more spheres of social life, they also provide means for elites who control them to exercise power and advance their political and economic interests (Weber [1921] 1978). Scholars who examine organization control have shown that at the turn to the twentieth century capitalists hired scientific managers to experiment with techniques to increase control over the labor process. These scientific managers collected information from workers and centralized it in planning departments where engineers used it to establish formal rules to control the labor process (Braverman 1974).

In the middle decades of the twentieth century, decision-making theorists demonstrated that the capacity of elites to control managers in large and complex organizations is constrained by bounded rationality: limits on rationality that are affected by unclear preferences, limited information, and the cognitive abilities of individual decision makers (Simon 1957). These decision-making theorists showed that superordinates attempt to overcome bounded rationality and increase their control over subordinates by establishing premise controls, which limit the search for alternatives in the decision-making process (March and Simon 1958). Other organizational researchers point out that bounded rationality cannot be completely eliminated and that premise controls and other formal controls have unintended consequences (Perrow 1972; Burawoy 1979). Research in this tradition shows that formally rational controls caused widespread inefficiencies in the decision-making process in corporate American during the middle decades of the twentieth century. In response to the capital accumulation crisis in the 1970s and early 1980s, like the earlier period when elites increased their control over the labor process, capitalists and their top managers implemented scientific management principles to increase control over the managerial process. They hired engineers and other technical experts to collect information from production managers, centralize that information into computerized information processing systems, and use it to develop premise and other formal controls that limited the discretion of lower and middle-level managers (Prechel 1994).

ORGANIZATIONS AND THEIR ENVIRONMENTS

Another line of research in organizational sociology examines the relationship between the internal organizational structures and the environment. There are two distinct types of organization-environment theories. The “weak form” of the organization-environment hypothesis stresses how organizations respond to environmental forces. Organizational ecology, which borrows from the biological model of natural selection, conceptualizes organizational populations as aggregates of organizations that are alike in some respect (e.g., newspapers). Organizations are considered part of a larger system that must adapt in order to survive. This perspective stresses the importance of structural isomorphism, which denotes a fit between the organization and its environment (Carroll and Hannan 1995). However, organizational adaptation is limited by inertia, which includes internal politics and increased age, size, and complexity. In the absence of adaptation to the environment, organizations will cease to exist.

Neoinstitutional theory also represents the weak form of the organization-environment hypothesis. This perspective examines organizational fields: a recognized area of institutional life with key suppliers, resource and product consumers, regulatory agencies, and other similar organizations (DiMaggio and Powell 1983). Once an organizational field is established, three mechanisms cause organizations to become homogeneous. First, mimetic behavior occurs when organizational technologies are poorly understood, when goals are ambiguous, or when the environment creates symbolic uncertainty. When these conditions exist, organizations model themselves on the dominant organization in their field. Second, normative behavior entails professionalization, which includes efforts by practitioners of an occupation to define the conditions and methods of their work, control the supply of new producers, and establish a cognitive base and legitimation for their occupational autonomy. Third, coercive pressures emerge from political and cultural influences. This neoinstitutional perspective assumes that an autonomous state creates public policies and laws (e.g., antitrust, product safety) and is capable of making corporations and other organizations comply with those laws.
In contrast, the “strong form” of the organization-environment hypothesis suggests that corporations and other organizations are capable of influencing public policies that are designed to control and regulate them. Resource dependence theory maintains that the environment constrains organizations, and organizations depend on other organizations for resources (Aldrich and Pfeffer 1976; Pfeffer and Salancik 1978). This perspective also maintains that the key to survival is the ability to acquire and maintain resources from other organizations in the environment. To reduce dependencies that limit their prospects for autonomous action and survival, organizations set up strategies to manage their environments.

ORGANIZATIONS AND PUBLIC POLICY
The strong form of the organization-environment hypothesis is consistent with research by political sociologists who show that business elites use networks of organizations to influence public opinion and public policy (Domhoff 2006), and economic sociologists who maintain that the behavior of individuals and organizations can only be understood by examining the social relations in which they are embedded (Granovetter 1985). Other researchers maintain that the universalizing assumptions in many social theories can be misleading and that the strong form of the organization-environment hypothesis is historically contingent (Prechel 1990). Historical contingency theory of corporate political behavior maintains that although elites are always politically active, the level of elite political activity varies over time. When the condition of economic uncertainty is high (e.g., periods of low or unstable profits), corporations become more politically active, and they pressure state managers to implement policies to attain economic stability and predictability and to preserve the social relations in capitalist society (Prechel 2000). Although capitalists and their top managers do not always have a coherent conception of the relationship between their economic goals and the means to achieve those goals, they engage in political behavior to transform public policies in order to create the conditions that better advance their profit-making agendas.

Historical contingency theory explains the three major corporate form changes in the largest U.S. firms between the 1880s and 1990s. First, in the 1880s and 1890s, business elites lobbied states to pass formal laws to give industrial corporations the right to use the joint-stock holding company. This corporate form holds the majority of the stock (i.e., more than 50 percent) of legally independent subsidiary corporations. The embeddedness of the holding company in an environment with little regulatory control created opportunities for capitalists to consolidate many independent companies into giant companies such as AT&T, General Motors, and U.S. Steel Corporation. By the 1920s, stock overvaluation and other forms of malfeasance were widespread in many holding companies (Berle and Means 1932). To reinvigorate and sustain capitalism after the Great Depression, the Franklin D. Roosevelt (1882–1945) administration set up public policies to limit the use of this corporate form. These policies included a tax on the transfer of capital between subsidiary corporations and the holding company. By increasing the cost to operate the holding company, this capital transfer tax contributed to the deinstitutionalization of this corporate form. After this legislation was passed, corporations began to restructure into a multilevel-subsidiary form where product lines are organized as divisions inside a single corporation. By 1960, the multilevel-subsidiary form prevailed in corporate America (Chandler 1962).

In response to the capital accumulation crises of the late 1970s and early 1980s, corporate America mobilized politically to replace the institutional arrangements that were established during and after the New Deal. These market-driven neoliberal policies included: (1) redefining antitrust regulations that prohibited large corporations from merging with others operating in the same market; (2) eliminating the tax on capital transfers from subsidiary corporations to parent companies; and (3) dismantling regulatory control over the banking and financial industry. Now, corporations were allowed to engage in behaviors that were previously illegal or not viable, including using new forms of financing to merge or acquire other large corporations and organize their new and existing corporate entities as subsidiaries in the multilevel-subsidiary form. This multilevel-subsidiary form has a parent company at the top of the corporate hierarchy that operates as a financial management company, with two or more levels of legally separate subsidiary corporations embedded in it (Prechel 2000, p. 12). By 1993, 65 percent of the one hundred largest U.S. industrial corporations used this corporate form (Prechel 2000, p. 244). As occurred during the late nineteenth and early twentieth centuries, this multilevel-subsidiary form provided a means to create giant corporations such as Exxon-Mobil, Chevron-Texaco, and ConocoPhillips. The embeddedness of this corporate form in these new institutional arrangements also created opportunities to overvalue corporate stock and to conceal financial malfeasance (Prechel 2000, p. 265).

CORPORATE CRIME
Following the 2001 bankruptcy of Enron Corp., civil and legal investigations showed that Enron’s management used the multilevel-subsidiary form to transfer capital between legally independent corporate entities and manipulate its financial statements (Prechel 2003). Self-interest-seeking with guile was not limited to managers in the few corpo-
rations that the media focused on. Between January 1995 and May 2005, the Commodity Futures Trading Commission, the Department of Justice, and the Securities and Exchange Commission filed 457 allegations against 151 (i.e., 30%) of the 500 largest U.S. corporations. In 2005 alone, the Federal Bureau of Investigation pursued 405 corporate fraud cases that resulted in an additional 317 convictions (FBI 2005). However, many executives who engaged in corporate malfeasance were not accused of wrongdoing or held responsible for misleading the public because deregulation made many social acts legal that were previously illegal or not viable.

Unlike in the 1920s, when most stock was owned by the upper classes, the expansion of mutual funds created means for the working classes to invest their retirement and savings into corporate securities. As a result, the working classes lost billions of dollars due to corporate chicanery and malfeasance in the 1990s. Estimates suggest that $2.1 billion was wiped out from the employee pension plan at Enron alone and that $40 billion was lost from employee pension funds in general.

ORGANIZATIONS AND INEQUALITY

Political mobilization by corporations and wealthy individuals was not limited to deregulating corporations. During the same period that public policy was changed in ways that created opportunities for corporate malfeasance, elites financed political action committees, think tanks, and lobbying organizations to transform public policy in ways that lowered taxes on wealthy individuals and corporations. This policy shift also included a reduction in social programs for the poor.

By 1990, family income inequality increased to the highest level since 1947, when the U.S. government began compiling these data, and continued to increase into the twenty-first century. The very rich benefited most in this redistribution of income and wealth. Whereas the top 1 percent of American income earners received 9.3 percent of the total income in 1979, this group received 17.8 percent of the total income in 2000 (Mishel et al. 2005, p. 62). Although the rich have always held a large percentage of the wealth in American society, wealth inequality also increased during the 1980s and 1990s. Whereas the wealthiest 1 percent of the population held 33.8 percent of the nation’s total net worth in 1983, it had increased to 38.1 percent by 1998 (Mishel et al. 2005, p. 282).

SUMMARY

The strong form of the organization-environment hypothesis suggests that the power of elites is derived, in part, from their capacity to control organizations and to use organizations to change their environment. Beginning in the 1970s, corporations and wealthy individuals used their wealth and power to decrease government regulation, increase corporate property rights, and extend free markets. These new institutional arrangements resulted in a historic turning point characterized by reduced regulatory oversight, lower taxes on corporations and wealthy individuals, higher rates of corporate chicanery and malfeasance, and increased inequality.

Prechel, Harland. 1994. Economic Crisis and the Centralization of Control over the Managerial Process: Corporate
Organizations, Peasant

Peasants—and peasant organizations—exhibit enormous diversity across time and space. Since the origin of state societies, smallholders, tenant farmers, sharecroppers, squatters, and landless laborers have participated in local organizations—some formal and others informal—to coordinate planting, cultivation, and harvesting; to administer irrigation systems; to exchange labor; to acquire inputs and market harvests; and to demand from those in power fairer prices, lower taxes, and access to land and other resources. In many parts of the world, peasant insurgencies against elites and colonial powers involved thousands or even millions of rebels drawn from among the rural poor. Twentieth-century peasant wars—such as the Mexican and Chinese revolutions and the Vietnam War (1957–1975)—brought massive social upheavals and reshaped geopolitics at the world level. In the late twentieth and early twenty-first centuries, organizations of peasants and small farmers helped to stall global trade negotiations and to reformulate policies in such areas as poverty alleviation, genetically modified crops, agrarian reform, and environmental sustainability.

Peasant and farmer cooperatives have existed in Europe and the Americas since at least the late nineteenth century. Most have been organized around the production and marketing of particular commodities, but many have involved machinery services, input purchasing, savings and credit, transport, and retail businesses. Cooperatives in most countries are barred from political advocacy activities, but many national- and international-level cooperative federations attempt to work for their members’ interests in governments and multilateral institutions.

Peasant and farmer associations that lobby or employ pressure tactics to defend their members’ interests are found virtually everywhere, including in developed countries where only a small portion of the economically active population works in agriculture. Unions of agriculturalists in France, the United States, and Canada exercise substantial political influence. In poorer countries, such as Ecuador and Bolivia, peasant and indigenous movements contributed to toppling national governments in the early twenty-first century. Even in China, where the government does not tolerate independent political organizations, rural unrest is widespread and has led to major administrative reforms, such as reductions in the taxes agriculturalists pay to local governments.

Scholars and activists have long debated the role of outsiders in forming peasant organizations. While rural people have had improved access to education in recent decades, through either government programs or nongovernmental organizations, a broad consensus exists that effective peasant associations usually require some outside leadership, at least in their initial stages. At the same time, it is now widely recognized that many rural people are increasingly cosmopolitan, with experience in urban areas and abroad that equips them for organizing and leading peasant movements.

Social scientists once distinguished between farmers, who had a commercial orientation, employed hired labor, and operated with advanced technology, and peasants, who were subsistence-oriented and used family labor and rudimentary technology. These ideal types have proven problematical as the rural poor adopt modern technologies, as agriculturalists in developing and developed countries collaborate around issues of common concern, as rural residents migrate to cities, and as peasants and farmers themselves emphasize their commonalities and downplay differences. Moreover, in many languages the terms equivalent to peasant—the French paysan or the Spanish campesino, for example—are more inclusive, meaning simply “people from the countryside” and including many farmers.

Transnational peasant organizations have a long history. The Farmers’ Institutes extension program originated in Canada in the 1890s and spread to the United States and Britain. Following World War I (1914–1918), peasant political parties—termed “the Green International”—held power in several eastern European countries. The Associated Country Women of the World was founded in 1933 and claims a membership of nine million in 365 participating societies in seventy countries. The Paris-based International Federation of Agricultural Producers, formed in 1946, includes many organizations of large
farmers and some peasant associations. The global farm crisis of the 1980s, marked by plummeting commodity prices and skyrocketing prices for fossil fuel–based inputs, sparked a new wave of cross-border peasant organizing, much of it directed against the General Agreement on Tariffs and Trade (GATT) and later the World Trade Organization (WTO). The Via Campesina, or Peasant Road, a militant international peasant and farmer organization that emerged in the early 1990s, has been in the forefront of campaigns to take agriculture out of the WTO and to implement “food sovereignty” policies. The Via Campesina has nearly one hundred member organizations in Asia, Europe, Africa, and the Americas. These include the Brazilian Landless Movement, the U.S. National Family Farm Coalition, the National Farmers Union of Canada, the Peasant Confederation of Peru, the Assembly of the Poor in Thailand, the Nepal National Peasant Women’s Association, and the European Farmers Coordination.

ORIENTALISM

Orientalism refers principally to the academic study during the eighteenth, nineteenth, and early twentieth centuries of the peoples, languages, and cultures of North Africa, the Middle East, and, to a lesser degree, South Asia. In art history, the term refers to a school of European painters of the nineteenth century who took the peoples of these regions as their primary subjects. Since the publication of Edward Said’s (1935–2003) widely influential study titled simply Orientalism (1978), the term has become pejorative, suggesting a critical orientation or mode of representation that privileges the Western over the Eastern or idealizes the East in a manner that reflects European desires and political and economic interests.

What is called, after Said, orientalist discourse, developed during the era of most active European colonialism, from the early 1800s to World War I (1914–1918). Among the first important works accurately called orientalist were those produced by figures associated with colonialist endeavors in North Africa and the Middle East, including the massive, twenty-four-volume Description de l’Égypte, produced by approximately 160 scholars who accompanied Napoléon Bonaparte (1769–1821) on his ultimately failed expedition to conquer Egypt in 1798. The Description, completed in 1829, is typically orientalist in, on the one hand, the idealization of Egyptian people and places in its many beautifully rendered images, and, on the other, its overall concern with defining and classifying all the cultural and physical aspects of Egypt toward the ultimate objective of controlling its people and natural resources.

The nineteenth century can rightly be called the orientalist era in the arts, as works across the spectrum of literature and painting drew on the myth of the Orient that was being produced by the functionaries of colonialism and the scholars of philology. While French painters such as Eugène Delacroix (1798–1863) and Jean-Léon Gérôme (1824–1904) are widely regarded as the preeminent orientalists in the visual arts, the movement was widespread and included Frederick Arthur Bridgman (American, 1847–1928), Frederick Goodall (British, 1822–1904), Louis-Joseph Anthonissen (Belgian, 1849–1913), Ludwig Deutsch (German, 1855–1935), and Leopold Carl Müller (Austrian, 1834–1892). Orientalist literary artists include Rudyard Kipling (1865–1936), Edgar Allan Poe (1809–1849), Joseph Conrad (1857–1924), and Arthur Rimbaud (1854–1891), to list only a very few.

Muslim women were a particular focus of orientalist artists. The “slave market,” “harem,” and “bath” received seemingly endless treatments. Gérôme’s images characteristically give the impression of the voyeur who has lifted or pulled back the “veil” to reveal the hidden mystery of the Orient. Women’s bodies are erotically on display, often, in fact, under examination by some Arab buyer or slave trader. The precise response of a European audience to such images is difficult to ascertain, but generally the
erotic construction of an Arab “other” appealed to a patriarchal sense of superiority and interest in control.

The matters of the European sense of superiority and interest in control can also be seen in orientalist scholarship. Non-Western societies were described as backward and barbaric, fundamentally incapable of social, political, or technological modernization. An important point is that the works of orientalist scholars were often not intentionally or explicitly motivated toward the interests of Western power. The assumptions of superiority and control were embedded in the scholarship, often despite the fact that an individual scholar might regard his or her subject very sympathetically. However, it is certainly true that whatever the disposition of the orientalist scholar, his or her work was a critical part of the general body of knowledge that facilitated and justified the control and exploitation of colonized peoples.

The publication in 1978 of Said’s study unleashed a fierce and continuing debate. The debate is wide ranging and contains multiple positions, though it can be roughly divided between two groups. Some believe Said’s work has overly politicized the academic study of non-Western peoples and unfairly characterized the work of devoted scholars. Others, particularly the generation of scholars who pursued their graduate work in the later 1980s and 1990s, hold that Said’s work is a particularly valuable contribution to the broad examination of the ideological assumptions and effects of intellectual works that purport to be disinterested.

Whatever the multiple positions in this rich debate, the influence of Said’s volume has been tremendous. Orientalism has been translated into at least thirty-six languages, including Hebrew and Vietnamese, gone through multiple editions, and is certainly one of the most cited works in the humanities and social sciences since 1978. The critique of orientalist work is at the center of entire new disciplines, such as postcolonial studies, which is concerned with the struggle of non-Western peoples to meaningfully represent themselves and their social, political, and cultural concerns to both Western and non-Western audiences and institutions.

O-RING THEORY

Michael Kremer formulated the O-ring theory in 1993. His article, “The O-ring Theory of Economic Development,” published in the Quarterly Journal of Economics, presents a production function in which production consists of many tasks, all of which must be successfully completed for the product to have full value. Mistakes can be extremely costly reducing the product’s value. The name O-ring comes from the accident of the space shuttle Challenger that exploded because one of the components, the o-rings, failed.

The production function has two crucial assumptions. The first is that workers must be sufficiently imperfect substitutes for each other; that is, it is not possible to substitute several low-skill workers for one high-skill worker. Skill is defined as the probability of a worker successfully completing a task, $q$. The second assumption is that there are strong complementarities among inputs; that is, if there are $n$ tasks, output, $y$, is given by multiplying the $q$-values of each of the $n$ tasks together. Assuming that firms are risk-neutral, labor is supplied inelastically and labor markets are competitive, production is given by:

$$E(y) = y = k^n \prod_{i=1}^{n} q_i$$

where $k$ is capital and $B$ is output per worker with a single unit of capital if all tasks are performed perfectly. Profit maximizing firms choose a level of capital, $k$, and the skill of each worker, $q_i$, facing a wage schedule $w(q)$ and a rental rate, $r$. The first-order condition associated with each of the $q_i$ is

$$\frac{dw(q)}{dq} = \frac{dy}{dq} = k^n B$$

Thus, the increase in output a firm obtains by replacing one worker with a slightly higher skill worker, leaving everything else constant, must equal the increase in its wage bill necessary to pay the higher skill worker. Thus the wage schedule is a function of worker skill.

As the derivative of the marginal product of skill for the $i$th worker with respect to the skill of the other workers is positive,

$$\frac{d^2y}{dq_i d(q_{-i})} = k^n B > 0,$$

firms with high $q$ workers in the first $n - 1$ tasks place the highest value on having high-skill workers in the $n$th task, so they bid the most for these workers. As a result workers of the same skill are matched together in firms.

Kremer stressed that this production function is consistent with many stylized facts such as: (1) wage and pro-
ductivity differentials between rich and poor countries are enormous; (2) firms hire workers of different skill and produce different quality products; (3) there is a positive correlation among the wages of workers in different occupations within firms; (4) firms only offer jobs to some workers rather than paying all workers their estimated marginal product; and (5) income distribution is skewed to the right. Assuming sequential production in which the highest $q$ workers are allocated to the later stages of production it is possible to show that: (1) poor countries have higher shares of primary production in gross national product (GNP); (2) workers are paid more in industries with high value inputs; and (3) the effects of efficiency wages, bottlenecks, and trade restrictions are magnified. When the number of tasks, $n$, is endogenized it is possible to show that: (1) rich countries specialize in complicated products; (2) firms are larger in rich countries; and (3) firm size and wages are positively correlated. Finally, when skill is endogenized as the product of investment in education or effort Kremer showed that there is some level of education subsidy that improves welfare. Although many of these predictions of the model may be due to a variety of causes, together they suggest that O-ring production functions are empirically relevant.

Kremer stressed that if strategic complementarity is sufficiently strong one may have multiple equilibria and each may be inefficient. Therefore, there is room for public policies to move the economy to a preferred equilibrium. According to Michael Todaro and Stephen Smith’s 2003 work, one of the limitations of the model is that it falls short on practical policy implications.

The applications of the O-ring theory are wide. In 2006 Charles Jones adapted it to study the role of knowledge in the theory of economic development. Alberto Dalmazzo’s 2002 work combines the O-ring production function with efficiency wages; the workers employed in a firm with a more complex production process should earn higher wages than identical workers that work on identical tasks in firms with less complex production processes. Tuomas Pekkarinen’s 2002 estimates for the Finnish metal industry find evidence supporting this hypothesis.

In the O-ring theory productivity is associated with the job rather than with the worker, which raises questions about how workers get access to the higher productivity jobs. Peter Doeringer and Michael Piore’s 1971 work shows that internal labor market analysis promotions have the role to allow workers to get access to the higher productivity jobs and firms to extract the maximum effort from workers. The economy may be characterized by dual labor markets in which one sector offers high wages, stability, and good working conditions and the other sector offers low wages, high turnover, and poor working conditions, pressing one back to the structuralist analysis.

Kremer acknowledged that his paper combines Sherwin Rosen’s 1981 analysis of multiplicative quality effects with Gary Becker’s 1981 analysis of matching in marriage markets. However, some of Kremer’s ideas were advanced by the theory of stratification formulated by Kingsley Davis and Wilbert Moore in 1945 and developed by Arthur Stinchcombe in 1963 and Stinchcombe and T. Robert Harris in 1969. According to Davis and Moore, stratification in all societies was viewed as an unconsciously evolved device by which societies assured that the most functionally important positions would be filled by the most capable persons. Stinchcombe, focusing upon organizational rather than social stratification, hypothesized that the more complementary are individual contributions to total production, the greater will be the inequality of rewards. Stinchcombe and Harris anticipated the production function presented by Kremer in which the case of interdependence of activities in production is modeled as the product of the probability that every worker will be working.

João Ricardo Faria
ORTHODOXY

The concept of orthodoxy is variously used as: (1) a historically specifically located term; (2) a descriptive-analytic term to describe traditions or writers that may not describe themselves by that term; and (3) a titular self-description in various religious communities (e.g., Modern Orthodox Judaism, Greek Orthodox Church). Often, orthodoxy is juxtaposed with orthopraxy, whereby orthodoxy would apply more appropriately to cognitivist traditions, such as Christianity and its emphasis on faith and theology, rather than to traditions that define themselves along behavioral lines, such as Judaism and Islam with their emphases on religious law. This juxtaposition is artificial, however, since Judaism and Islam, as well as Christianity, develop discourses of orthodoxy and authenticity.

The historical origin of the concept of orthodoxy (from the Greek word for correct or normative faith) as the antonym of heresy (Greek, “faction”) can be traced back to early Christian literature. Conceptually, orthodoxy emerges as a by-product of the early Christian practice of heresiography, whereby the two antonyms were aligned with other oppositional pairs, such as, importantly, truth and its perversions. To a large degree, the heresiographers opted to define orthodoxy by what it was not—namely, the aberrant heresies—rather than to formulate what orthodoxy actually entailed. First-century writers such as Josephus (37–c. 100 CE) could still employ the term heresy in the sense of “school of thought,” as in his description of the various schools of thought in first-century Judaism (Pharisees, Sadducees, Essenes, and potentially Zealots). Hence, this first-century phenomenon is most often described as sectarianism rather than as a struggle for orthodoxy. To Josephus, none of these groups constituted an orthodox versus a heretical version of Judaism, or an exclusionary normative Judaism from which the others were to be excluded as deviant marginal groups. What distinguishes the heresiographical texts of the second half of the second century and onward from first-century writers such as Josephus is precisely this shift in meaning from heresy as a school of thought, still subsumed under the umbrella of the larger category term of Judaism (in Josephus’s case), to heresy as a deviant aberration from the true religion, hence to be excluded from its boundaries of identity. Only the latter allows a notion of orthodoxy as the true, authentic version of Christianity (and subsequently Judaism) to emerge.

It may be debatable as to the degree to which the early Christian leader Paul already engaged in a heresio-graphical practice in his epistles without resorting to the concept of heresy when in his Epistle to the Galatians (1:6–7) he denounced his opponents as those preaching “another gospel” and thereby “perverting the gospel of Christ.” However, it appears that the first author of what turned into the genre of Christian heresiography was Justin Martyr (100–165 CE) with his Refutation of all Heresies, a text that is no longer preserved. Subsequently, Irenaeus’s treatise Adversus omnes haereses (Against All Heresies, 185 CE) drew on Justin’s work, and from then on heresiographies present a distinct genre of Christian literature and theology. Around the same time, Jewish writers, such as the authors of the earliest Rabbinic text, known as the Mishnah (c. 200 CE), began to adopt heresiographical practices.

The early Jewish and Christian debates were carried out in a context in which the writers lacked the support of institutional or political authority. A case may be made that these strategies of self-representation contributed to, if not entirely caused, the institutional consolidation of the Catholic Church, ultimately backed by the political authority of the Roman Empire, and the rabbinical leadership of the Jewish community at the end of the late antique period.

The heresiographers employed a number of strategies to render persuasive their notion of the true and therefore authoritative or normative version of theology and practice. One strategy to establish authenticity was to attribute historical or chronological priority to their norms. For example, the early rabbis claim that their traditions or their “oral Torah” was already given to Moses on Sinai (Mishnah Avot 1:1), and the Christian heresiographers attribute their teachings to the first apostles and ultimately Jesus himself. The historical priority of authentic traditions is subsequently secured by chains of traditions that lead from the source to each respective heresiographical author. Heresies then are represented as groups (“them”) that split off from the normative tradition and perverted it, versus the projected “us” who continue the authentic and original tradition. This classic strategy of self-representation is employed in various other religious contexts, often in order to disguise innovative practices and beliefs. In the case of early Judaism and Christianity, this strategy was so successful that modern historians have often assumed such claims to be descriptive rather than recognizing them for their rhetorical work.

Another strategy of the heresiographers was to adduce and at the same time reduce the origin of what they wished to portray as false belief to a founding figure whose name would give the denounced faith its name. Paul juxtaposes the idea of following Christ with merely following Paul, Apollo, or Cephas (Peter) in his argument against divisions in the early church communities (1 Cor. 1:12).
Subsequently, heresiographers provide lists of named and supposedly nameable groups who may not have described themselves by those names, as Justin Martyr does in his *Dialogue with Trypho*: “Some are called Marcionites, some Valentinians, some Basilideans and some Saturnalians, and some others by other names” (Martyr 1930, p. 70), just not the name Christians. This strategy allows for contrasting these marginalized categories of groups with the universal unnamed category employed to promote the appearance of authenticity, whether that is represented by terms like orthodoxy and catholic (Greek, “universal”) in the Christian case, or “Israel” versus groups such as Sadduceans and Boethusians in the early Rabbinic case. Both these strategies—the attribution of historical priority to that which is promoted as authentic, and the reduction of opponents to marginal movements contrasted to one’s own universality—are repeated in numerous other conflicts, mostly of a religious nature.

While the concepts of orthodoxy and heresy have specific historical origins, and are mostly used in the contexts of religious practices and religious studies as well as in sociology of religion, they have come to be used more broadly in various other disciplines and subject matters. Any established tradition or symbolic order perceived as truth, as the law, or as political consensus can be described as orthodoxy, and anyone diverging therefrom as heterodox or heretic. A discipline of study may be legitimated by one normative methodology, leading to a perception of innovative approaches as heterodox or heretic.

In the social sciences, Pierre Bourdieu (1930–2002) elevated the concepts of orthodoxy and heresy to methodological principle in his analysis of social behavior, accompanied by a third concept, doxa. In his classic work *Outline of a Theory of Practice* (1977), he defines orthodoxy as “a system of euphemisms, of acceptable ways of thinking and speaking the natural and social world, which rejects heretical remarks as blasphemies” (Bourdieu 1977, p. 169). Hence, orthodoxy is always a social fiction, a socially established convention in the realm of discourse. Doxa, on the other hand, refers to the “pre-verbal taking-for-granted of the world that flows from practical sense” (Bourdieu 1990, p. 68). At times, Bourdieu maps all three terms on class distinctions in that doxa is the product of a system of domination. Accordingly, he defines doxa as the viewpoint of the dominant, which disguises itself as universal, neutral, or objective, and which the dominant classes have an interest in defending, whereas the dominated have “an interest in pushing back the limits of doxa and exposing the arbitrariness of the token for granted” (Bourdieu 1977, p. 169). Doxa is a stronger tool of domination because it is “an ensemble of fundamental beliefs which do not even need to affirm themselves in the guise of an explicit dogma, conscious of itself” (Boulluec 2001, p. 346), that is, orthodoxy. Hegemony and orthodoxy are interchangeable. The heretic then is the person, a prophet or homo academicus, who discovers some unrecognized belief about the world that supplies the means of thinking the unthinkable.

Bourdieu is not the first to translate the concepts of orthodoxy and heresy or heterodoxy, originally coined in a religious context, into analytic vocabulary for sociological and political analysis, but his is the most influential to date.

Charlotte Elisheva Fonrobert
ORTIZ, FERNANDO
1881–1969

Fernando Ortiz was a public intellectual known for his interdisciplinary studies of Cuba’s popular cultural traditions, particularly Afro-Cuban culture and its multietnic African heritages. Recognized as the founder of the social sciences and specifically of anthropology and ethnomusicology in Cuba, he was born in Havana on July 16, 1881, but spent his youth in Minorca, Spain. After completing high school in Barcelona, he returned to Cuba in 1895 to study law at the University of Havana. Within three years he decided to complete his studies at the University of Barcelona because of the turmoil from the war of independence against Spain. Upon earning his bachelor’s degree in law in 1900 and a doctorate in law from the University of Madrid in 1901, he returned to Cuba where he agreed to serve the newly established republic by accepting a three-year term as a diplomat. While in Italy, he met Cesare Lombroso (1835–1909) and Enrico Ferri (1856–1929), positivist criminologists who, along with Spanish scholars (e.g., Rafael Salillas, Manuel Sales y Ferré, Bernaldo de Quirós, and Dorado Montero), influenced his early thinking on crime.

Following his diplomatic service, Ortiz taught law at the University of Havana. Even before this academic appointment began, he investigated Cuba’s criminal underworld, particularly African- and to some extent Chinese-descended criminals. His first book, *Hampa afro-cubana: Los negros esclavos* (Afro-Cuban Underworld: The Black Wizards, 1906), was a “criminal anthropology” of the deviance that constituted *la mala vida* (the evil life). Ortiz’s study of Havana’s criminal underworld, particularly *brujería* (witchcraft) and the notorious ritual murders of white children purported to be a part of it, was grounded in the Spencerian evolutionism and biological determinism advanced by Lombroso, who wrote the book’s preface. Ortiz’s treatise reinforced the racist notion that lawlessness and social disorder were attributable to those of African origin, whose savagery impeded national development.

In later work, Ortiz shifted to a perspective contesting the idea that Afro-Cuban culture was inconsistent with modernity. He moved beyond a criminological approach to an ethnographically informed anthropological framework for understanding the cultural integrity of the multiple religions that were homogenized and confused with antisocial “black” magic. This important shift was, in part, the result of influence from the Haitian-descended ethnographer Rómulo Lachatañeré (1909–1952), who pushed Ortiz to use a more culturally appropriate lexicon for Afro-Cuban religions and ritual specialists.

Ortiz developed a methodology that stressed the significance of culture and history. In *Hampa afro-cubana: Los negros esclavos* (Afro-Cuban Underworld: The Black Slaves, 1916), he began to clear the ground for an analysis that would eventually lead to the elaboration of a theory of transculturation, his major contribution. He introduced this neologism in *Contrapunteo cubano del tabaco y el azúcar* (Cuban Counterpoint: Tobacco and Sugar, 1940), a watershed book establishing him as Cuba’s leading social scientist dedicated to illuminating the complex dialectical interplay between culture, history, and political economy. Coined as an alternative to acculturation, the more conventional concept in U.S. and British cultural and social anthropology, transculturation elucidated the “complex transmutations of culture” (Ortiz [1947] 1995, p. 98) and the ongoing interchanges, reciprocities, and tensions in a national context in which diverse peoples have experienced “loss or uprooting” (p. 102), as well as the accomplishment of creating new cultural forms and a social system for ordering the lives of both the dominant and the dominated. Transculturation was invoked in conjunction with the analogy Ortiz often made between Cuban national identity and *ajiaco*, an always-changing stew. The centrality of Africa’s contributions to that stew was a key insight discernible even in his earlier work.

Misrepresented as functionalist in Bronislaw Malinowski’s (1884–1942) introduction, *Cuban Counterpoint* was an innovative work written in an allegorical style. At once a cultural and an economic history, the book interpreted Cuba’s development in terms of the oppositional and mutually constituted agency of its two major commodities, sugar and tobacco. Through the poetic deployment of these entities as metaphors, he offered a holistic analysis of these paradigmatic commodities as both material objects and socially constructed historical actors in a world shaped at once by human practice and the wider structural forces that constrain it. Critical of reductionist interpretations of Cuba’s colonial and neocolonial experience, Ortiz’s contrapuntal method offered an alternative to the dominant canons of anthropology and history as established within the Northern Hemisphere.

Ortiz’s far-ranging contributions included laying the foundations for the progressive reform of Cuba’s criminal justice system, writing on the indigenous origins of Cuban culture, and serving as a Liberal Party representative in congress. The bulk of his contributions to Cuba’s intellec-
tual life and public culture stemmed from his seminal research on all aspects of Cuba's African-influenced, orally transmitted traditions. He validated the use of Afro-Cuban as an analytical construct while insisting that Afro-Cuban cultural forms were integral to a unified Cuban national identity. He also addressed the problem of racism and the workings of race as a social rather than biological category. Major publications in his later life included *La africanidad de la música folklórica de Cuba* (The Africanity of Cuba's Folkloric Music, 1950), *Los bailes y el teatro de los negros en el folclor de Cuba* (Black Dances and Theater in Cuba’s Folklore, 1951), and the five-volume work, *Los instrumentos de la música afrocubana* (Instruments of Afro-Cuban Music, 1952–1955). These mature works reflected the comparative method Ortiz used to treat "the processes of social contact, their impact on the historical effects of the slave trade, and different African ethnic groups and their transculturation" (Font and Quiroz 2005, p. 250).

Throughout his career, much of which was based at the University of Havana, he founded a number of journals, associations, and institutions to provide outlets and support for research on Afro-Cuban culture and other components of Cuban national identity. He died in Havana on April 10, 1969.

**OSCEOLA 1804–1838**

Osceola (ah-see-oh-la) was a warrior and chief of the Seminole Indian tribe during the Indian removal from Florida to unsettled U.S. territory in the West during the early 1800s. His significance in the academy and the social sciences is linked to issues related to Native American identity and the political relationship between Native Americans and the U.S. government. Significant as well is his historical relationship to African slaves and contemporary African Americans’ tenuous relationship to Native American tribes—the Seminoles in particular, but also the Choctaw, Creek, Cherokee, and Chicksaw, who were removed from their original homelands in the southeastern United States to their present, primary home in Oklahoma.

Osceola is seen as a major figure in securing the rights of Seminoles and other native peoples during the colonial period—not through signing agreements and treaties with agents of the U.S. governments, as some tribal leaders had done, but through guerrilla warfare tactics that kept the U.S. military at bay for a long time and so slowed the removal of Seminoles and the taking of Seminole lands. Osceola has also been viewed as a symbol of the ancestral mixture that formally and informally linked African peoples to the Indian tribes, a link that fuels contemporary claims to tribal government benefits.

The Seminoles in Florida were remnants of other Indian tribes that fled to Florida and established a lifestyle, culture, and politics that were indigenous and
self-governing. Osceola strenuously objected to the United States’s offer to buy Seminole Florida lands in exchange for removal and settlement to open territory west of the Mississippi. Though his position differed from those of many of his tribal brethren, he found allies among another group of wanderers who had fled to Florida—free Africans and fugitive slaves who had several years before merged with the Florida Seminoles. These freedmen and fugitives—referred to by the Seminoles as Estelusti—joined the faction of Seminoles led by Osceola in opposing relocation, fighting alongside them in the Seminole Wars.

Although these “Black Seminoles” were loyal to the Seminole tribe, adopting many of their customs, intermarrying, and settling with them in the new Indian Territories in Oklahoma, Texas, Louisiana, and other surrounding states, neither the Seminoles nor whites during that period recognized them as official tribe members. Later, when the Dawes Act of 1887 required a census of Native American tribal members, Black Seminoles—referred to as Freemen—were counted as part of the tribal role, and received allotments of tribal lands. As a result of Jim Crow laws enacted after Oklahoma statehood, Black Seminoles were physically separated from their Seminole tribal brethren and their legal status as official tribal members was called into question. The ensuing controversy lasts until the present, in large part due to the refusal of the Bureau of Indian Affairs to grant official certificates of Indian blood to Black Seminoles not originally on the Dawes rolls. Blacks were officially enrolled as tribe members and recognized as such by the federal government. In 1991 the federal government awarded the Seminoles $56 million for their Florida lands, but nonblack members of the tribe claimed that the black members had no claim to share in the award. This prompted black members of the tribe to file suit in federal court; in one argument, they pointed to the original relationship their ancestors had with Osceola (and one of his wives who was African descent) and their loyalty in fighting with him as a reason that they should be recognized as full tribal members.

OTHER AMERICA, THE
SEE War on Poverty.

OTHER, THE
The term other is used in a variety of contexts. In the most basic sense, the other is used with a small o to depict the manners or processes by which perceptions of others are attained. This is the subject of much research in psychology, neurology, cognitive science, and philosophy of mind. Psychologists, particularly childhood psychologists, postulate that perceptions of the other proceed inter alia from processes of contrast, comparison, and analogy through which the self sets itself apart from, first, those who are close—mother, father, and other kin—and, second, outwardly to distant “strangers” (Klein 1964; Erikson [1950] 1993). It is thus understood that consciousness of the self depends upon processes that affect distinct characteristics to others.

Often in the social sciences and humanities the other is signified by a capital O. For instance, following in the footsteps of Georg W. F. Hegel ([1807] 2003) and Edmund Husserl ([1929] 1999), continental European philosophy investigates the question of otherness in conjunction with the tendency of the self to conceive all things after one’s own likeness. This tendency results in the desire of the ego to “feel at home” in any philosophical speculation or scientific inquiry and yet separate or above the process of inquiry. The Other emerged in this context with either a transfigured or disfigured essence, no longer a reflection of itself and unaware of itself. This “Other” is a product of the self or at least only knowable first because of one’s awareness of the self.

Post–World War II existentialists such as Jean-Paul Sartre sought to “transcend” the subjugated position of the Other by examining the role that self-consciousness plays in any inquiry (Sartre [1943] 2001). Then, from Russia and eastern Europe, Mikhail Bakhtin, Emmanuel Levinas, and Julia Kristeva brought to the terms other and othersness different inflections and connotations (Bakhtin [1986] 1993; Levinas 2000; Kristeva 1994). These authors founded their theories of the Other on personal or collective experiences in more or less cosmopolitan contexts of heterogeneous mixes of disparate languages and cultures in Europe. They stressed their own otherness based on difference, that is, either individual characteristics of persons or systematized identities of classes of peo-
ple. For Levinas, the Other is the very condition of one's own existence. The Other is not any particular person, but instead an entire category that he calls “Otherness,” which makes being and self or “I” possible, thus reversing the presupposition of phenomenologists such as Husserl and other continental thinkers who began all philosophical inquiry with the self. This line of argument has also concerned feminist thought, accepting the problem of the Other as the first philosophical question (Butler 2005) but insisting on the re-examination of the highly gendered notions of the ego, desire, subjectivity, and ethics (Beauvoir [1949] 1989).

The Other has not always been an interlocutor or object of reciprocal engagements. Karl Marx, Friedrich Nietzsche, Michel Foucault, and others have indicated difficulties involved in transcending the immediacy of the self in ideology or inquiry into social, political, and economic relations (Marx [1844] 1998; Nietzsche [1901] 1967; Foucault 2005). Anticolonialists and postcolonial theorists have constructed similar arguments that posit that the colonial enterprise was guided by an ideology that degraded the markers of culture, arts, and science in non-European societies to the status of folklore, myths, shamanism, and the like. Then, the colonized other was not merely different. Placed under the sign of the native (the secular equivalent of infidel), the other was deemed inferior and variably educable according to race, geography, and culture (Said 1979). It is now widely accepted that colonialists projected their own inadequacies or fears onto the colonized (Trouillot 1997). Even today, political discourse is rife with notions of rogues, failed states, and doctrines of democratic peace that assume inherent differences based on region, religion and culture, and race.

However, the stereotyping of the other(s) remains intractable because it seems to be integral to thought processes. It has benign or deadly consequences, depending on intent and circumstances, extending from simple acts of discrimination to ethnic cleansing and other crimes against humanity. As a result, neuroscientists and other specialists of the brain have undertaken inquiries on the nature of the brain, particularly how the brain generates and processes perceptions of self and the other. Indeed, scientists continue to wonder about the extent to which the brain and the mind can be made to transcend self-consciousness and affect to relate differently to desire, interest, and their pathos (Damásio 2000). For social scientists, the question of self and other centers on the means to a higher order of politics, where all might feel at home aided by scientific practices that ensure human survival (Connolly 2002).

OTTOMAN EMPIRE

The Ottoman Empire (c. 1290–1922) provides a vivid example of durable and successful state building in world history. A late medieval creation, the Ottoman state achieved world empire status in 1453 because of its conquest of Constantinople. During the surrounding several centuries, it was among the most powerful states in the world. Although geography and luck played roles, the success of the empire mainly derived from pragmatic and flexible Ottoman policy-making and considerable open-
ness to innovation, including military technology. At its peak, the empire covered parts of Asia, Africa, and Europe. Its extent is suggested by this partial list of successor states: Albania, Bosnia, Bulgaria, Egypt, Greece, Iraq, Israel, Jordan, Kuwait, Lebanon, Montenegro, Romania, Saudi Arabia, Serbia, Syria, and Turkey.

Expansion slowly faded into memory and territorial contraction began thanks partly to developments elsewhere in the world, notably the rise of capitalism and industrialism in Europe and then elsewhere, and to the New World wealth that poured into Europe. At wealth flowed elsewhere, the Ottoman Empire was unable to compete and lost its preeminent position; by about 1800 it had become a second-class economic, military, and political power. Within the empire innovation faded, partly because entrenched bureaucrats, statesmen, and military personnel acted to protect their children's positions and closed entry to newcomers.

During the nineteenth century a successful series of programs measurably strengthened the state and its military. The bureaucracy grew both in size and in the scope of its activities, now not merely collecting taxes and providing security but also taking responsibility for the health, education, and welfare of its subjects. Yet, the empire fell defeated in World War I (1914–1918) and was partitioned by the Great Powers, notably Great Britain and France.

In its domestic polity, the Ottoman state underwent continuous change. The Ottoman ruler, the sultan, began as one among equals, but between about 1453 and 1600, sultans ruled as true autocrats. Thereafter until about 1826, sultans reigned, but others in the imperial family and other inhabitants of the palace—often in collaboration with provincial elites—maintained real control of the state. Then, bureaucrats and sultans vied for domination of the state apparatus. In sum, the sultan presided over the imperial system for all of Ottoman history, but actually personally ruled for only portions of the fifteenth, sixteenth, and nineteenth centuries. Also, political power almost always rested in the imperial center and, depending on the particular period, extended into the provinces either through direct military and political instruments or indirectly through fiscal means.

A combination of religious and secular laws regulated the lives of Ottoman subjects. Under Ottoman state authority Muslim, Christian, or Jewish judges presided over the legal affairs of their respective communities. Often, however, subjects of all religions used the Muslim courts because rulings from such courts might have greater weight than those from Christian or Jewish sources. In addition to this religious law, the state routinely passed its own, secular, ordinances, often with lip-service adherence to Islamic principles. In the nineteenth century, when a flood of ordinances and regulations marked the presence of an expanding bureaucratic state, even the lip service frequently fell away in favor of scientific management.

This was an agrarian empire that, again, changed considerably over time. Most Ottoman subjects were and remained cultivators, raising a wide variety of different crops for subsistence and for sale. The particular mix of crops changed over time. Cereals remained dominant throughout the Ottoman period, but important new crops emerged at different times, for example, tobacco in the seventeenth century. In theory, the vast majority of land was owned by the sultan, but in practice, generally, land users enjoyed security of tenure. Sharecropping was widespread and the major vehicle by which goods came to market; most holdings were small. Commercialization of agriculture considerably developed in the eighteenth and nineteenth centuries. Ottoman manufacturing, for its part, remained largely small-scale and handcrafted, with some late mechanization. During the seventeenth and eighteenth centuries foreign markets for Ottoman manufactures fell away, but producers continued to enjoy a vast domestic market for their wares; in the nineteenth century export markets emerged for Ottoman rug makers and silk spinners, who usually were women working outside their homes. In transportation and communication there were important technological breakthroughs during the second half of the nineteenth century, including steamships, railways, and the telegraph.

Ottoman intercommunal relations are hotly argued, and many popular stereotypes persist around the “terrible Turks” who slaughtered Ottoman Christians. For nearly all of Ottoman history, this stereotype is not true. For most of its duration, the Ottoman Empire can be characterized fairly as a tolerant political system. At times, the Ottoman state led the way in extending tolerance to minorities. For example, at the end of the fifteenth century Ottoman sultans welcomed the large Iberian Jewish population that the new Spanish monarchs were expelling from their own kingdom. More generally, the key to Ottoman success and a major reason for its longevity lay in the tolerant governmental treatment of those who did not share its professed religion. This tolerance was based both in practical politics and in the dictates of Islam. Until the 1870s the majority of Ottoman subjects were Christians and the state’s official religion was Islam, which required that the Muslim state protect the religious rights of its Christian and Jewish subjects. The Ottoman Empire, for nearly all of its history, was a multinational, multireligious entity that did not seek to impose Islam on its subjects. This fact often has been forgotten in the confusion surrounding the end of the empire and the emergence of the Ottoman successor states, but it remains true nonetheless. Overall, the Ottoman system recognized dif-
ference and protected those differences so long as subjects rendered obedience and paid taxes. Until the eighteenth-century era of the Enlightenment, minorities in the Ottoman world likely were treated better than in Europe. Atrocities did occur, but they were exceptions in the rule of a generally admirable record of intercommunal relations over the 600-year life span of the Ottoman Empire.

OUGHT SELF

The ought self is a particular type of self-guide. Broadly, self-guides are representations of the self. Proposed by E. Tory Higgins (1987), self-guides are involved in self-regulation such that they provide standards for the self. The ought self is a self-guide attached to ideas about who persons feel they should be or should become. These selves are typically concerned with safety and responsibility. In contrast to the ought self is the ideal self, which represents who individuals want to become and is generally concerned with hopes and wishes.

Particular self-guides are associated with different affective experiences. Individuals who perceive a large discrepancy between their actual selves and their ought selves are more likely to experience an agitation-related affect, such as anxiety and guilt, while individuals who perceive their actual selves to be more proximal to their ought self-guides experience a relief-related affect, such as calmness.

Individuals may also differentiate between various sources of their self-guides. They may construe that their self-guides represent their own ideas of who they should become or that they represent their ideas of whom others think they should become. Regardless of the source of the guide, discrepancies involving the ought self are associated with an agitation-related affect.

The experience of discrepancy from an ought self incites a negative affect. This negative affect is unpleasant, and individuals generally want to avoid it. Consequently they will self-regulate or attempt to bring their actual selves more in line with their self-guides. In this way they reduce the perceived discrepancy between their actual selves and their ought selves. When the discrepancy is reduced, a less negative affect is experienced. In their 1994 study E. Tory Higgins, Christopher R. J. Roney, Ellen Crowe, and Charles Hymes found that individuals concerned with ought selves tend to use avoidance strategies in the process of self-regulation.

Individuals may differ in the extent to which they tend to use ought selves as self-guides. In his 1997 article, Higgins considers those who are more likely to use the ought self to be prevention-focused. That is, they are more likely to pursue goals that are related to safety and responsibility. In contrast, individuals who are more likely to use ideal selves as a self-guides are referred to as being promotion oriented.

Developmentally, parental factors may be associated with using ought selves in self-regulation. In 1998 Nanmathi Manian, Timothy J. Strauman, and Nancy Denney investigated the relationship between recollections of parental styles, temperament, and tendencies to use ought versus ideal selves. They found that individuals who recall their parents behaving in ways they perceived as rejecting were more likely to possess discrepancies between their actual selves and their ought selves. The researchers attribute this finding to an increase in the salience and usage of negative outcomes for these individuals. Additionally they found that both negative and positive temperament characteristics predicted actual and ideal discrepancies, while only negative temperament characteristics predicted actual and ought discrepancies.

OUT-SOURCING
Outsourcing is a process whereby an organization contracts with an outside entity to perform some business function previously done “in-house.” Practically any function can be outsourced, from manufacturing labor to customer service. The spatial distance between the core firm and the contractor can vary greatly. Offshoring denotes an outsourcing of business functions to a contractor located in a foreign country. Domestic outsourcing occurs within a single country, and can even involve two firms located directly adjacent to one another. The temporal relationship between core and contractor firms can also vary, from a decades-long partnership to temporary services rendered for a single day. Due to the complex nature of the phenomenon and the inadequacy of existing data, no precise metric is available with which to quantify the extent of outsourcing or its growth over time. Those interested in the issue of measurement should consult Robert C. Feenstra (1998). Social scientists generally agree, however, that outsourcing has proliferated globally since the 1970s.

To explain this proliferation of outsourcing, scholars situate it in relation to the larger phenomenon of economic globalization. In this view, the mid-twentieth century was dominated by large oligopolistic firms catering to regional markets within the nation-state. These firms were vertically integrated; that is, they controlled both supplier and distributor firms. They located their headquarters and production facilities proximate to supplier and consumer markets. Work was organized to achieve economies of scale and to maximize the volume of goods produced. Workers were in turn offered job security and generous wages.

Commencing in the 1970s, several major changes to the organization of economies and states dramatically transformed ideas of how a successful business should be designed. Business leaders now sought to “pare down” their organizations, by outsourcing all but a small core of essential functions. These streamlined firms would then be integrated into a web of strategic alliances with other firms around the world. But what were the changes that led to the emergence of what Manuel Castells (2000) calls a “network society”? First, firms experienced increased competition due to a deregulation of business relationships and the removal of barriers to trade across nations. Second, the ownership structure of firms underwent a transformation, as institutions purchased large portions of corporate stock. While individual shareholders are typically passive, institutional investors actively demand that managers maximize short-term profits. Third, advances in communications and transportation technology (especially personal computers and Internet access) enabled the coordination of production across great distances.

Intensified competition, a shareholder conception of control, and new technology increased the feasibility and attractiveness of outsourcing. As Paul Osterman (1999) documents, outsourcing decreases labor costs insofar as contracting firms pay on average lower wages and offer fewer benefits. Outsourcing also relieves the core firm from the responsibility of ensuring that working conditions meet state regulations. In the United States, for example, should a contracting firm be found to have forced employees to work overtime, it and not the core firm would be found culpable. More generally, outsourcing is believed to maximize flexibility. Temporary workers may be contracted to meet seasonal fluctuations in business activity, and production processes can be quickly reengineered to match changes in consumer demand, while relationships with suppliers can be terminated should production schedules be altered.

The proliferation over the past three decades of offshoring and domestic outsourcing has invoked considerable debate within nations. It is important to consider the points of view of two main parties: states and workers. Governments of states targeted by firms as sites of outsourcing can take a range of positions. At one extreme is a developmental state actively encouraging investment. At the other is staunch opposition to outside investment, most likely when the outsourced activity is perceived as vital to national security. For example, in April 2006 plans to outsource the inspection of incoming containers at U.S. ports to a Dubai-based company were canceled after U.S. Congressional leaders protested over potential security risks.

When confronted with proposals by domestic firms to offshore production, governments may accuse firms of behaving greedily or unpatriotically. This is especially the case when the outsourcing will entail plant closings, or when the domestic firm is outsourcing not for economic survival but to achieve a higher rate of return on investment overseas. Politicians may even pass legislation to discourage foreign investment by domestic firms. Such protectionism, however, represents what Robert Reich labels “vestigial thought” (1992, p. 154), insofar as it remains wedded to a vision of unitary firms producing and selling goods within a single nation-state. In fact, managers, when deciding to offshore production, are merely responding to the shifting rules of the larger game of global capitalism. Governments intent on protecting domestic jobs would be wiser to cooperate to reshape the rules of this game rather than demonizing individual players.

Like states, workers in existing core firms may view outsourcing as against their interests. After all, the flexible
labor markets required by global capitalism entail the replacement of secure jobs offering middle-class incomes with insecure jobs and low wages. The competition among states to attract investment capital is in fact often labeled a “race to the bottom.” Yet workers and their unions are hampered in their capacity to take action against individual firms, since strikes or work stoppages may only quicken the pace at which work is outsourced. As Jeffrey Sallaz (2004) has documented, unions lack the means to influence the rules of the game at a national or global level, and so fight to slow the pace at which work is outsourced from core facilities to allow older workers time to adjust to the “new economy.”

To conclude, as competitive global capitalism has eclipsed oligopolistic national capitalism, outsourcing has emerged as a strategy used by private firms to cut labor costs and increase flexibility. Of immediate interest to social scientists in the coming years will be the question of how the economic trend toward outsourcing is affected by political developments involving the global “war on terror,” heightened border security, and resurgent nationalisms.

OVERACHIEVERS

The motivational basis for human-achievement behavior has interested psychologists for decades. Research has linked basic psychological theory to applications in education, business, and industry where achievement is critical. Striving for success pervades social interaction in the classroom, in the corporate boardroom, on the playing field, and even within families and friendships. Those who achieve success are viewed as productive members of society worthy of admiration and respect.

To some extent, practical concerns, such as the need to motivate children to set satisfactory goals in school and to address underachievement, generated scientific interest in achievement issues. Historically, underachievement (and overachievement) has been defined in objective terms according to the match between expectations and life outcomes, and psychologists have usually been concerned with these objective terms. Specifically, expectations for one’s performance are based on relatively objective criteria. For instance, people set expectations of their potential based on past performances or on the evaluations of significant others (e.g., parents, teachers). In Western society, standardized tests (e.g., the SAT) are common as a practical and seemingly objective basis for expectations of future performance. When someone performs below (e.g., grade point average) the level expected (e.g., by aptitude scores), that is underachievement. When underachievement is identified, educators marshal effort to help people realize their full potential.

Educators have paid little attention to the mirror image of underachievement: overachievement. When someone performs better than predicted in school (or anywhere else), that is overachievement. Overachievement presents no real problem to solve. Doing well is highly regarded, so it is not surprising that educators have neglected to study it. When someone outstrips objectively based predictions of their performance, prevailing wisdom suggests reason to celebrate, not to intervene.

This traditional emphasis on objective achievement suggests that people might be expected to work tirelessly to ensure success. Yet, everyday observation reveals that people approach achievement in their everyday lives in many ways. Some people strive mightily, but others seem lazy and disengaged; still others take credit for outcomes that they appear not to have earned, and sometimes people flee from tasks when the prospects of failure or embarrassment become too great.

Social psychologists have studied the subjective experience associated with underachievement and overachievement. Findings show that there is a great deal to be learned about these experiences. In particular, the subjective experience of overachievers may be highly stressful and unpleasant and marked by anxiety, but uniquely defined by self-doubt. Specifically, the subjective experience of chronic self-doubt, coupled with intense performance concerns, appears to inspire overachieving behavior. Overachievers may expend heroic effort to cope with their chronic doubts.

One social psychologist coined the term John Henryism hypothesis to describe the psychological stress associated with the social and economic challenges faced by African Americans. The research links an increased risk of hypertension and other health problems among African
Over-attribution Bias

Americans to the stress of persistent, effortful coping in the face of socioeconomic challenges, a parallel to the experience of the fictional character John Henry, who outpaced the steam drill but died soon thereafter from the exertion. Like John Henryism, the stress of everyday overachieving may also have adverse health implications.

Ironically, overachievement can serve to enhance rather than diminish self-doubt in one’s natural talent. The effort of overachievers provides an alternative explanation to natural ability for any success they achieve. Moreover, these shaky assessments of ability generalize to shaky expectations of future potential. Sadly, overachievers may reap success beyond objective expectations but still doubt their own ability to reproduce success without enormous effort. Overachievers may ultimately enter a vicious cycle in which they cope with self-doubt by, once again, expending heroic effort to ensure that they can perform successfully again and again. High achievement and overachievement in the context of a group might even enhance self-doubt about an individual’s personal contribution, and produce shaky judgments about one’s individual talent and personal value to the group. The increased pressure to perform successfully in a public arena has been shown in research many times.

Some individuals experience high self-doubt without having the intense concern over performance that characterizes the overachiever. At a behavioral level, the lower concern with performance leads these individuals to employ a very different strategy than overachievers. These individuals may cope with self-doubt by employing the seemingly paradoxical strategy of deliberately sabotaging, or handicapping, their own performance. Like the overachiever, self-handicappers experience chronic self-doubt. Unlike the overachiever, however, self-handicappers are more concerned about the implications of failure as it relates to judgments about their ability; they worry that failure will be an indication (to themselves or others) that they lack ability. Thus, whereas the overachiever will expend heroic effort to avoid failure, the self-handicapper is willing to embrace failure (i.e., withdraw effort) to protect a basic perception of personal competence. They undermine their own performance in order to make the cause of their (perhaps failing) behavior ambiguous. Examples include alcohol use and abuse, procrastination, laziness, and any other behavior that could excuse failure.

Though speculative, the distinct psychological style of subjective overachievers can be traced to their early learning history. The budding overachiever may come to internalize the parental message that only successful performance can guarantee continued love and support. These early beliefs may lead overachievers to assign higher significance to successful outcomes than to exploring their actual talents.

Subjective overachievement has been distinguished in research from high achievement motivation (people show the same concern over successful performances, but seek achievement for personal satisfaction), perfectionism (people display intense preoccupation with successful performance, but do not necessarily experience self-doubt), and the imposter phenomenon (where self-doubt is present, but success is seen as unearned or illegitimate because it is due to luck, not effort).

OVER-ATTRIBUTION BIAS

The over-attribution bias, also known as “correspondence bias,” occurs when people attribute human behavior to whichever causal factor is most available to them. Behavior often “engulfs the field,” and people draw dispositional inferences that correspond to the behavior. When a person freely expresses a certain attitude, others assume that the person believes it. The same inference is biased, however, when observers know that a powerful other asked the person to express that attitude. The bias is most striking when it is the observers themselves who constrain the respondent’s behavior.

The common interpretation of the correspondence bias is that it constitutes a “fundamental attribution error”
(Ross 1977). This interpretation holds that people fail to fully discount the influence of a person's internal disposition as a cause of behavior. The error interpretation has been influential in social psychology because it implies that people are incapable of understanding the power of the typical social-psychological experiment, which is to demonstrate that subtle changes in a person's situation can dramatically change behavior.

Upon review, the idea that people fail to appreciate the power of social situations needs to be tempered. The correspondence bias reverses, for example, when people who know a person's disposition are asked to judge the strength of the situation. They continue to attribute behavior in part to the situation even when the behavior is freely chosen. Hence, the correspondence bias is generic rather than purely dispositional. People attribute behavior firstly to whichever causal factor they happen to be focused on, be it a property of the person or the situation, and then modulate this inference by considering the other, less salient causal factor. Because the former process is likely intuitive and automatic, whereas the latter is deliberative and controlled, the bias is larger when people are unmotivated or unable (e.g., because of distraction) to process all available information.

Most models of causal attribution are hydraulic in that they regard the total causal force directing behavior as a zero-sum quantity. As one causal factor is being favored, another one must yield. On this view, the correspondence bias reflects a failure to fully discount the primary and salient cause when the secondary cause is sufficient. For the explanation of everyday behavior, the hydraulic model is sometimes inadequate. For example, people often attribute aggressive behavior to an aggressive disposition. To do so, however, they require the presence of a facilitating stimulus, such as an insult or a threat. Whereas a hydraulic model suggests that inferences about an aggressive disposition should be stronger in the absence of provocation, an interactionist model recognizes that a situational cause (provocation) is necessary for a dispositional attribution. On this view, theories of personality that seek to capture individual differences by merely counting trait-related acts are likely contaminated by the researchers' correspondence biases.

The common tendency of attributing correspondence bias to people's dispositional failure to think logically may itself be an example of the very same bias. Correspondence biases are, after all, experimentally evoked when investigators limit the salience of the situational causes of behavior. Hence, it may be sufficient to attribute respondents' preference for dispositional inferences to the nature of the experimental situation.

OVER-CONTROL

SEE Farsightedness.

OVEREATING

*Overeating* is a relative term, defined as food consumption that exceeds energy expenditure. Chronic overeating typically results in obesity and is not uncommon. In fact, obesity is at epidemic proportions for all age groups, and is seen as a growing health threat not just in Western societies but also in much of the world. Risk for obesity increased markedly during the 1980s, an increase that is attributable to a complex combination of environmental, sociocultural, genetic, and behavioral factors.

Overeating can be either active or passive. Active overeating is largely the consequence of a convergence of sociocultural factors that most notably include aggressive mass marketing of energy- or calorie-dense foods (foods high in fat, refined carbohydrates, and sugar) and disproportionately large portions of food relative to individuals' actual caloric needs. Not coincidentally, such foods are easily accessible, widely available, relatively affordable, and highly palatable. Unsurprisingly, society has fallen prey to marketing influences, and consumption of such foods is on the rise. It is noteworthy that, as of 2006, the highest rates of obesity and obesity-related disorders in the United States are found in lower-income groups for whom the marketing of energy-dense, low-cost foods is most pervasive.

Active overeating is also part of the symptom complex of conditions such as bulimia nervosa and binge eating disorder. With bulimia, individuals experience a sense of being unable to control what and how much they eat, and they engage in recurrent episodes during which they very rapidly consume an abnormally large quantity of
food. This symptom is also a defining characteristic of binge eating disorder. A key distinction between bulimia and binge eating disorder is that with bulimia, individuals engage in dangerous methods of weight control (e.g., purging, fasting, and vomiting), whereas with binge eating disorder, individuals do not engage in such weight control efforts and, in fact, may be obese. Active overeating may also result from hypothalamic dysfunction, either due to genetic defects (e.g., Prader-Willi syndrome), physical injury, or pharmacological agents.

Although active overeating accounts for a substantial proportion of the high rates of obesity, passive overeating may best explain prevalence rates. There are several aspects to consider in passive overeating. First, as is perhaps obvious, individuals with an energy-dense diet who consume food equal in quantity to individuals with a lower-energy diet have an overall greater energy intake. Second, lower-energy diets are most satiating, whereas energy-dense diets are least satiating: Consumption of a greater quantity of energy-dense foods is required to achieve equal levels of satiety. Thus, passive overeating is the unintentional, but inevitable, consequence of a diet that is energy-dense. Given that it is also a prime factor in the energy balance equation, physical inactivity compounds the issue. Technological advances promote an increasingly sedentary lifestyle that, in combination with active or passive overeating, further subverts the energy equation, resulting in ever-rising obesity rates.

Although research on pharmacological interventions to treat obesity is ongoing, lifestyle changes are likely to remain central features of any intervention. It may, however, require major macrosystemic social change to effect significant improvement in our nutrition and physical activity.

OVEREMPLOYMENT
Little is as damaging economically, socially, and psychologically as depriving people of income and job opportunities, from unemployment and underemployment. Overemployment, however, refers to depriving the employed of desired time. Individuals are defined as overemployed when they are prepared to sacrifice income proportionally for a given reduction in their work hours but cannot do so at their current job or a suitable comparable job. For example, an overemployed individual would like to work no more than forty hours per week (including overtime), but he or she is forced by the employer to work fifty hours per week.

The conventional microeconomic model of individual labor supply assumes that workers desire to work a certain number of hours per week based on their expected wage rate, nonwage income, and preference for nonwork uses of time. Insightful models have incorporated the possibility that at least some workers are often not able to realize a preference for fewer work hours because of constraints that are imposed by employers or the labor market (Dunn 1996; Feather and Shaw 2000; Altonji and Oldham 2003). Employers face a variety of incentives and pressures that may lengthen the hours of work demanded from each employee (Rebitez and Taylor 1995; Contensou and Vranceanu 2000). Whenever hours demanded exceed workers’ desired number of hours supplied to their job, workers supply “surplus” hours (Lee and McCann 2004). This condition may persist indefinitely when the alternative job with shorter hours actually results in relatively lower levels of utility than working surplus hours (Kaufman and Hotchkiss 2006). Hours mismatches or inconvenient hours do not create compensating wage differentials for working (Altonji and Paxson 1992; Reynolds 2004). Overemployment becomes a wider social problem to the extent that it creates symptoms of “overwork,” such as fatigue and stress, which heighten the risk of workplace accidents, illnesses, and work-family time conflict.

As with unemployment, there are cyclical, frictional, and structural macroeconomic sources of overemployment (Altman and Golden 2004). Further, measuring the overall rate of overemployment has proven tricky. The estimated rate is sensitive to the wording of survey questions and response options. Estimates range from 6 percent to over 30 percent of the U.S. workforce (Bell and Freeman 1995; Altman and Golden 2004), lower than the rate in comparable countries (Bielinski, Bosch, and Wagner 2002). Moreover, the overemployment rate may diminish with time if preferences are “endogenous.” Workers unable to “get what they want … eventually want what they get” (Schor 2005, p. 46). The distribution of overemployment is highest among women with preschool children, those in professional and technical health occupations, and those with long workweeks (Golden 2005). Overemployment may take the form of an unfulfilled wish to switch from longer to standard or part-time hours or to decline mandatory overtime work.
Conventional economists discount overemployment for two reasons. One is the suspicion that stated preferences for shorter hours would actually be acted upon. In addition, the rate of overemployment is a low priority because it is dwarfed by the rate of underemployment (Kahn and Lang 2001). However, a proactive approach would favor regulatory incentives that compel employers to shift the excess hours of the overemployed toward the underemployed within their workplace or industry.

OVERFISHING

Overfishing occurs when the stock (biomass) of a fish species has been subjected to a rate or level of fishing mortality (usually from commercial fishing) that has reduced it below its capacity to maintain an established fishing (harvest) yield. This yield is usually specified as the maximum sustainable yield (MSY), defined as the maximum amount of fish that can be removed from the biomass on a sustained basis while maintaining the same stock level, given the stock’s biological growth function (dynamics). Overfishing is inherently a biological concept, although it is fundamentally tied to economic behavior because it involves fishing pressure or intensity beyond an optimum level. The model used to evaluate it is thus called a bioeconomic model.

To more specifically define overfishing it is necessary to determine what fishing level would be optimal in terms of the biological stock, or not constitute overfishing. The first step is to define the biological growth function, which is generally attributed to Milner B. Schaefer (1954; see also Anderson 1986). Given his assumption of a logistic growth equation, a sustainable yield curve can be drawn as a parabola, expressed in terms of either the biomass stock (S) or fishing effort (E), as shown on the left and right hand side of Figure 1, respectively.

In an unexploited state (no mortality from fishing) the fishery is in a biological equilibrium where growth is zero, at the left-hand extreme of both curves in the figure. If fishing then begins, defined in terms of increasing fishing effort (days, or boat/crew), the fish stock falls (a movement to the right on the horizontal axis in both panels). The biomass (fish) growth that may be harvested (caught) on a sustainable basis rises, however (as indicated by the increasing yield on the vertical axis with a move up the
Overlapping Generations Model

The maximum possible sustained yield is attained at the very top of the curve(s), which shows the MSY fish stock ($S_{msy}$), the effort required to harvest that stock on a sustained basis if no shock changes the curves ($E_{msy}$), and the maximum catch attainable in that state ($C_{msy}$). If more fishing effort than $E_{msy}$ is applied to harvesting, however, the stock and thus sustainable catch decline (a movement down the right hand sides of the curves), because reproduction is not proceeding fast enough to counteract the exploitation. This is a state of overfishing, represented by the lower sustained yield (or mortality) than possible (such as at $C < C_{msy}$). The stock is thus overfished, characterized by a lower stock than at the MSY point ($S < S_{msy}$), and the fishery is overcapitalized ($E > E_{msy}$).

Overfishing is the likely outcome in an unmanaged fishery because it is common property or open access (no one owns the fish), so fishers will keep fishing as long as they find it profitable. Such overuse is generally expected for common property or common pool resources, a problem often called "the tragedy of the commons" (see Hardin 1968). That is, overexploitation of the stock occurs because without property rights fishing will continue until the average rather than marginal benefits of harvesting are equal to marginal costs. In the standard bioeconomic model this results in an effort level on the right hand side of the curve.

A primary goal of fishing management is thus to counteract the incentive to fish the stock down to an overexploited or overfished state. This can be accomplished by command and control policies such as limits on the total allowable catch or days at sea. Such policies still do not provide incentives for fishers to maximize the economic value of the fishery, which is best accomplished by conferring property rights on fishers to approximate a socially optimal outcome. Such programs can be difficult to implement, however, due to distributional and political issues about who is allowed to fish, how much revenue each fisher receives, and how such rights should be conferred (e.g., for free or auctioned off with the proceeds going to the public or to support fishery management).

OVERLAPPING GENERATIONS MODEL

Like other economic models, an overlapping generations model (or as it is widely known, an OLG model) is a simplified theoretical representation of complicated economic processes through a set of identities and equations that describe the behavior of various agents interacting with each other. The most distinguishing feature of an OLG model lies in the way it captures the changing behavior of consumers over different phases of their lives. Since consumers in an OLG model are modeled as individuals who live for $n$ periods ($n \geq 2$), people born in $n$ different periods (or $n$ different generations) coexist in any given period $t$. While consumers die at the end of $n$ periods, reproduction assures that there will be an infinite succession of consumers, each living for $n$ periods.

At the beginning of their economically active lives, individuals are endowed with a labor power that they can sell to firms (and may have goods or assets they inherit from the previous generation). They work when young and spend part of their labor and asset earnings on present consumption, saving the rest for financing their consumption when they are old. Thus, their old-age consumption is financed through savings they made while they were young and any returns to assets they acquired by using those savings. In other words, individuals must spread their income from the wages they earn by supplying their labor power to firms and the return on their assets over their lifetime such that they can continue to consume even after they are too old to work (or after they retire).
Consumers just starting their economic lives make their decisions on how much to spend on consumption and how much to save within each period ahead of them so as to maximize their lifetime utility. Profit-maximizing firms produce an output by employing labor supplied by young workers and capital supplied through their savings invested in physical capital. In essence, capital is part of the current output set aside to be used in production of the next period's output. Thus, the more individuals save for future consumption, the higher the expansion in the capital stock and, hence, the higher the rate of economic growth will be. As such, OLG models extend standard growth models by relating capital accumulation to savings that young adults make out of their earnings for the purpose of financing their old-age consumption. Within this framework, the long-run equilibrium (or the steady state) will be reached after the growth rate of the total capital stock in the economy has become equal to the population growth rate (or equivalently, after capital stock per worker has stopped changing over time).

Suggested first by French economist Maurice Allais in 1947, the concept of an OLG model was further developed in a 1958 article by Paul A. Samuelson (Samuelson and Allais won the 1970 and 1988 Nobel prizes in economics, respectively). While Peter A. Diamond also made a significant contribution to the OLG modeling literature through a 1965 article, the growth of this literature remained slow until the mid-1980s. The growing concerns over the upcoming burden of the retirement of baby boomers born in the 1940s and the 1950s on social security systems of industrial countries starting from the 1980s led to the realization that extending previous OLG models to incorporate social security was relatively easy, as they realistically captured the changing consumption and savings behavior of individuals before and after retirement. This development has revived interest in OLG models and attracted the attention of economists to the long-term economic effects of demographic developments.

In addition to purely theoretical models, a book by Alan Auerbach and Laurence Kotlikoff published in 1987 popularized the use of numerical solutions to large-scale OLG models with several generations in studying issues related to social security and the evolution of fiscal policy in different countries with different demographic structures. Numerous applied models were constructed thereafter to investigate the implications of changes in age profiles of populations for labor supply, savings, and fiscal balances, as surveyed by David Miles (1999). The realism of applied models has increased with the introduction of additional production sectors that produce distinct goods by employing capital and labor. Elaborate theoretical grounds for two-sector OLG models that allow the consumption goods to be distinguished from investment goods were laid out in an article by Oded Galor published in 1992.

Theoretical as well as applied OLG models have since proved particularly popular in analyzing the long-term economic consequences of the gradual aging of nations, a demographic process characterized by the increasing population share of the elderly due to declining fertility rates and increasing life expectancies during a country's demographic transition. As demographic projections pointed to the continuation of this trend in the decades ahead, modeling of demographics within the OLG framework became increasingly realistic. (According to the United Nations, the world's population, standing at less than 7 billion in 2006, will reach 9.3 billion by 2050. The number of people aged sixty or over is projected to more than double to nearly 2 billion during the same period. Furthermore, the elderly population itself is aging, with the eighty-plus age group making up the fastest-growing segment of the population.)

Despite variations in its timing and speed across countries, this demographic transition is expected to have important implications not only for future balances of the social security system and the time paths of age-specific public expenditures such as education and health care in a country, but also for the evolution of the supply of labor and capital. In most of the industrial countries where demographic transition started earlier than developing countries, the population shares of people older than the retirement age have already reached critical levels that signal financial trouble for publicly managed retirement systems. Likewise, the declining share of working-age population in these countries raises concern about contractions in domestic labor supply. Furthermore, because the elderly tend to spend more and save less, industrial countries are also expected to face changes in the ratio of savings to consumption in their national income, as well as in the composition of consumption.

These demographically induced developments are certain to affect not only investment and growth patterns of industrial economies but also the global allocation of resources by creating incentives for migration and by affecting the patterns of international trade and capital flows. They must, thus, have implications also for developing countries, even though these countries' own demographic transition processes lag behind industrial nations. The growing awareness of this situation prompted renewed interest in the OLG works of the early 1980s, such as the articles by Joel Fried and Willem Buiter studying issues related to trade or capital flows between nations. Oded Galor and Shoukang Lin made important contributions to the theoretical analysis of international trade using OLG models. Such authors as Andrew Mountford and Emily Cremers showed in different articles that
dynamic trade equilibrium in an OLG framework may not always imply welfare gains for trading partners, contrary to predictions of static trade models. In a particularly interesting 2001 article based on results from an applied OLG model developed to study trade between a middle-income country at the beginning of its demographic transition and a group of high-income countries with aging populations, Turalay Kenc and Serdar Sayan showed that trade and capital flows serve as a channel for the middle-income country to import the effects of population aging in its trade partners ahead of time.

OVERLENDING

Overlending describes the behavior of creditors that extend loans to borrowers that are unable or unwilling to repay the debt on its original terms. The borrowers may be individuals, firms, or sovereign countries. Creditors span the range of public and private-sector institutions, although much of the analysis of overlending focuses on the lending patterns of banks. Overlending can lead to unsustainable debt burdens for the borrower and financial losses, both for the lenders and the broader economy, particularly in cases where disruptions of debt service lead to financial crisis.

Theoretical explanations for overlending often cite imperfect information and moral hazard as factors contributing to unsustainable lending booms. Imperfect information about the borrower or economic conditions contributes to uncertainty in assessing credit risk. Moral hazard, where the existence of insurance or guarantees encourages greater risk taking, may also contribute to overlending. Overlending can also take place when excess liquidity and competitive pressures between lending institutions contribute to loosening of credit standards. Obvious profligacy, including loans to insiders, corrupt businesspersons, or relatives where the loan may be made with no expectation of repayment, may also take place in the absence of strict credit standards.

In the United States, the government has crafted policies to inhibit overlending. Bank supervision aims to contain the moral hazard associated with deposit insurance and prudential standards prohibit the most egregious lending practices. Nevertheless, the savings and loan crisis, which lasted from the late 1970s through the 1990s, included elements of overlending. While structural problems related to restrictions on lending rates and the resulting interest-rate mismatch were underlying causes of the crisis, some thrift institutions had large loan losses attributed to insider loans or to lending in riskier markets. The policy solution to the savings and loan crisis therefore involved an enhanced supervisory structure as well as an infusion of funds to recapitalize troubled thrifts institutions.

By the early 1980s, the Latin American debt crisis was vying with the savings and loan crisis as the most significant financial calamity. In a paper presented at a World Bank symposium, Jack M. Guttentag and Richard J. Herring argued that competitive pressures on banks and
overoptimistic assessments of borrower capacity contributed to unsustainable levels of lending. In their book *The Loan Pushers* (1988), William A. Darity and Bobbie L. Horn pointed out that while competitive pressures can lead to overlending, moral hazard might also have played a role since commercial bankers may have viewed the International Monetary Fund (IMF) and other public-sector actors as guarantors that would orchestrate a bailout. Darity and Horn also detailed factors that might have contributed to imprudent borrowing, but recognized that policies to prevent future financial turmoil must be based on a clear understanding of the roles that creditors as well as borrowers played. Institutional weaknesses would require institutional reform.

Despite efforts at such reform, international debt service problems reemerged in the mid-1990s. These problems involved bond holders as well as banks, and came after a rapid expansion of credits to firms and sovereign borrowers in Latin America and Asia. International financial institutions also increased their lending to the least developed countries, and by the end of the 1990s many poor countries, especially in Africa, were carrying unsustainable debt burdens. There has been a concerted policy response to the events of the 1990s: debt relief, a greater share of aid in grants, and promoting compliance with international financial standards and codes. All of these policy interventions are aimed at preventing the re-emergence of overlending.

**OVERPOPULATION**

When laypersons speak of overpopulation, often they are referring to exceeding the carrying capacity of the Earth. Carrying capacity is an often-used term with many definitions, a common element of which is the number of people able to sustain life within the limits of the earth's environment. A definition of overpopulation should go beyond carrying capacity per se and take into account the state of the environment—whether the condition of the natural world allows for a comfortable existence and whether the current generation will leave the Earth inhabitable for the next generation.

An issue in assessing the dynamics of overpopulation is how best to create a reliable parameter for its measurement. What level of comfort among the various alternatives—the American, the Guatemalan, the Japanese—should be the ideal? The answer to this question determines the relevant issues of the environment to be considered and the number of people who may be sustained. Consider the amount of meat in a typical diet, the culturally defined idea of personal space, or the number of comfort goods that need to be produced and the resources involved in their production. The United States is the world's biggest consumer of natural resources, though its population makes up only 5 percent of the world's population. If the world were held to the American standard, the Earth's carrying capacity would soon be exceeded.

The concern with overpopulation is not new. During the eighteenth century Thomas Robert Malthus declared that overpopulation was bound by nature to occur. He assumed that, if left unchecked, populations tend to increase geometrically and food and sustenance arithmetically. Malthus advised moral, that is, sexual restraint and late marriage as preventive checks to prevent population increase. He also noted that such positive checks as wars, pestilence, and famine would keep the death rate high, also resulting in a slowing down of population growth. In 1968 Paul Ehrlich made similar predictions in his popular book *The Population Bomb*. Unlike Malthus, he gave special attention to the degradation of the environment by humans. Ehrlich's solutions were much more dramatic. He reasoned that billions of people must starve to death for there to exist an equilibrium between population and the environment. Neo-Malthusianist concerns continued into the 1970s with the Club of Rome's report on *Limits to Growth* and E. F. Schumacher's influential 1975 book *Small Is Beautiful*, which spawned a counterculture with the same name. Benjamin Friedman noted in his 2005 study that portions of these themes are reflected presently in the anti-globalization movement.

Is the world overpopulated? The world's population in the year 2006 was estimated to be over 6.5 billion strong and growing. These growth dynamics need to be considered in any discussions about overpopulation. The Population Reference Bureau projects a world population in 2050 of 9.3 billion people (Population Reference Bureau 2006). The United Nations reports that before 2050 more than 80 percent of the world will have below-replacement fertility (U.N. 2002), and their medium population projections for 2050 are very similar to the PRB's projection.
Around 3.5 billion people were added to the world’s population between 1950 and 2000; this was the fastest rate of population growth in recorded world history (UNPD 2002). By mid-century the world is expected to add another 3 billion to its population. Though the absolute number of people in the world in 2050 will have increased, its rate of growth will have slowed. There are now forty-four countries with fertility rates below the replacement level; their populations are projected to diminish in the next forty-five years. Most of the growth in the world will occur in the less developed regions of the world. Families will be smaller all over the world; indeed there has already occurred a marked decrease in average family size in most of the countries of the developing world.

If the planet is already overtaxed by 6.5 billion people, then coming decades will likely be a time of disquiet and suffering over much of the world. When considering overpopulation, one must weigh the well-being of the individual against that of all of Earth’s inhabitants. Rights that form the base of many nations, such as the rights to property, reproductive rights, and economic rights, will likely be less well defined in a situation where the issue of overpopulation is paramount. The right to purchase and use land may need to be regulated in order to protect the environment. Families may be forced to limit their numbers, and individuals may have to decrease their consumption to conserve natural resources and protect the environment.

It is difficult to construct the parameters of overpopulation. Considering the health of an entire world versus a single nation seems contrary to much of human history. Population projections for the rest of the century are subject to much variation depending on fertility patterns, thus further complicating the issue. As the world competes for limited resources, it is quite possible that the issue of overpopulation will be an issue of concern in many countries.

**OVERPRODUCTION**

Say’s law of markets is commonly understood, by friends and foes alike, to deny the possibility of general gluts. Overproduction theories are one of the ramifications of the opposition to this view; they evolved through direct confrontation with the proposition they were denying, in its various interpretations. These criticisms share the general standpoint that crises (or cycles) are to be explained in terms of some systematic divergence between production and consumption. Whereas Say’s law only admitted accidental disequilibrating causes (such as wars or exceptionally abundant or scarce crops) or temporary imbalances (due for instance to entrepreneurial miscalculations), the dissenters insisted on the general character of market gluts and pointed at causes intrinsic to the working of the system. Where dissenting views diverge is on the specific causes of disequilibrium. Overproduction theories of crises and business cycles emphasized troubles arising from the side of production, whereas the underconsumptionists instead attributed the disharmony to lack of effective demand, often stressing distributional factors determining lack of purchasing power or excessive saving. (The first representative of the latter view was J.C.L. Simone de Sismondi; other prominent writers in this tradition include J. A. Hobson, William Trufant Foster and Waddill Catchings, and some Marxists). The distinction, however, is somewhat artificial, for there is a certain complementarity and overlapping between the causes identified by overproductionist and underconsumptionist writers.

Say’s law emerged as the winner of the “gluts debate” after the Napoleonic wars. David Ricardo’s argument, that production is only undertaken with a view to sell and sales
only made with the intention of purchasing other goods thereafter, with its implication that disequilibria can only be temporary states of affairs resulting from exogenous events or miscalculation, gained wide acceptance. Thomas Robert Malthus’s contrary opinion, that the system’s development could be hindered, and unemployment would ensue, if the accrued production were not distributed in such a way as to “occasion the most effective demand for future production,” was only accepted by a minority of heretics (Malthus 1952, p. 10). From the 1840s onward, however, a growing number of writers questioned the validity of Say’s law. A first step (taken by John Stuart Mill, Karl Marx, and Wilhelm Roscher) consisted in rejecting the assumption that exchange was essentially equivalent to barter, by pointing out that money separates the acts of buying and selling and thereby makes crises possible. But this is only an abstract possibility. At the time, most authors believed that the factors turning this possibility into an actuality were linked to credit and speculation. Later, processes like hoarding, liquidation, and repayment of loans were added.

Marx’s theory of crises was the starting point of a number of overproduction approaches. His reproduction schemes showed that while harmonious growth is a logical possibility, it is not a necessity. One of the points on which Marx insisted was that advances in technology and organization imply an increase in productivity, and therefore diminish the value of wage-goods. If, in the short term, workers obtain increases in their real wages, the profit rate decreases below what capitalists considered customary, and production has to be stopped. The German-language branch of overproduction theories emphasizing producers’ losses (prominently represented by Arthur Spiethoff) built on this view. The American counterpart of this approach grew out of the distinction between “absolute” and “relative” overproduction: While it was admitted that there cannot be overproduction with respect to human needs, it was pointed out (by David A. Wells, Uriel H. Crocker, Arthur Twining Hadley, and Constant Southworth) that production can be in excess to demand to the extent that the price is not sufficient to cover costs inclusive of a remunerative or ordinary profit—although the notion of “ordinary” profits was questioned (by Thorstein Veblen).

A second group of overproduction theories stemming from Marx’s schemes of reproduction emphasized that there is no logical necessity that productive sectors grow proportionately and that maladjustments tend to amplify and spread to the whole system (M. I. Tugan-Baranovsky). Along this line we also find writers (Hans Neisser, L. V. Birck) who stressed the implications of technological progress, pointing out that when the vertical structure of production is altered, the preservation of the correct proportions becomes increasingly difficult and is likely to be disrupted by several minor causes. Another group of writers insisted instead on the fixity of fixed capital: Having acquired expensive machinery requiring maintenance costs even if not used, entrepreneurs find it rational to keep producing even at a loss (Crocker, Wells). In this view, overproduction is not so much an excess of goods as of productive capacity (William Smart, Scoville Hamlin).

Several other authors considered systematic impediments to the establishment of a stable equilibrium between supply and demand. Time lags, in particular, were invoked in this connection by Albert Aftalion and Mentor Bouniatian. They argued that a divergence between supply and demand would generate price differences inducing an adjustment, but that as production lags behind demand due to the time required to build plants, prices send the wrong signals and induce overproduction crises.

When such a view was incorporated into formal dynamics in the 1930s (in particular by Michael Kalecki), the business cycle came to be seen as resulting from the dynamic properties of the system and the need to stress overproduction gradually faded. The other contemporary business-cycle theories—the equilibrium and the real business cycle approaches—focus on equilibrium and thus dispense with an essentially disequilibriumist concept altogether.

OVERSHOOTING

Overshooting is a term used in macroeconomics and international finance to describe the behavior of the exchange rate after the economy is hit with a shock (i.e., an unanticipated event of sufficient magnitude such that it affects aggregate income, the general level of prices, or the aggregate volume of employment). Further, overshooting is a theoretical concept and is not always observed in the data. This concept was introduced into the economics literature by Rudiger Dornbusch (1942–2002) in his 1976 article “Expectations and Exchange Rate Dynamics,” which is the most-cited professional article in international macroeconomics.

Overshooting describes the fact that before the exchange rate gets to its new long-run value in response to a shock, it may initially move past or “overshoot” the new level to which it will eventually settle.

Figure 1 represents the response of the exchange rate (measured in U.S. dollars per euro) to an increase in the U.S. money supply. As one can see, in the short run the exchange rate overshoots (moves to a point higher than) its long-run value.

Theoretically, overshooting arises in an economic model that assumes: (1) exchange rates are flexible; (2) uncovered interest parity holds (i.e., the difference between interest rates in the U.S. and euro zone is equal to the expected rate of U.S. dollar depreciation); (3) money demand depends on interest rate and output; and (4) prices are fixed in the short run but they fully adjust to offset monetary shocks in the long run. Thus, in the long run, an increase in the money supply would be fully reflected in an increase in the price level, including the price of foreign currency, the exchange rate.

Since prices are sticky in the short run, they cannot adjust immediately, and therefore an increase in money supply would instead lower the interest rate in the United States. For the uncovered interest parity to hold, people should now be expecting the U.S. dollar to appreciate. At the same time, we know that in the long run the dollar exchange rate will converge to a more depreciated value; thus, immediately after the shock, the dollar has to depreciate by more than in the long run and then start appreciating, as shown in Figure 1.

The overshooting phenomenon is common to many modern theories in international macroeconomics that assume sticky prices in the short run. Thus, it is a necessary component of any macroeconomic forecast, as well as of the analysis of possible responses of the economy to monetary policy changes. Nevertheless, not all models, and not even all sticky-price models, predict overshooting in the behavior of the exchange rates.
The concept of overshooting helps explain an important empirical regularity—the fact that exchange rates are much more volatile than price levels or interest rates. Indeed, while prices adjust slowly and monotonically to their new long-run levels, exchange rates “bounce around.” In a world with numerous economic shocks, this leads to a high volatility of exchange rates and a much smaller volatility of prices.

The concept of overshooting does not help much in predicting exchange rates. This is partly due to the fact that one of the main assumptions of the model, the uncovered interest parity, is not borne out by the data. On the other hand, other models do not do a better job in predicting exchange rates than the overshooting model.

OVERTIME

Overtime work is a historical, legal, sociocultural, and economic construction. It typically refers to instances where an employee is working hours of labor in a given week (or per day or month) beyond some “standard,” “regular,” or “normal” hours. Overtime may be defined in terms of either national laws or workplace culture. The notion of overtime has changed over time, as these standards or norms have themselves changed. Indeed, laws place pressure on conventional norms and on the actual number of working hours (and vice versa). This explains why the connotation of overtime differs by country, time period, workplace culture, type of job, and employment contract.

In the United States, overtime work became codified as part of the 1938 Fair Labor Standards Act (FLSA). The FLSA was enacted both to counter the Depression era’s prolonged unemployment and the long, grueling workdays and workweeks for wage workers that predominated during the industrialization phase of capitalism prior to the 1930s. Unlike European countries’ statutory limits, the United States and other Anglo countries tend to apply only monetary incentives, the time-and-a-half pay premium requirement for hours worked by employees in excess of forty in a given week period to enforce the standard.

About one in five workers in the United States works extra hours for extra pay. Where there is no legally required pay premium for hours beyond forty hours, for those in exempt managerial, administrative, and professional jobs, the definition of what constitutes overtime work becomes hazier. About three in ten workers work longer than forty hours per week. More than one in five employees work extra hours because it is required by their employer. According to Juliet Schor’s The Overworked American: The Unexpected Decline of Leisure (1993), there is evidence that the long-run trend toward shorter average workweeks reversed course in the mid- to late-twentieth century in the United States. In 2000 Ronald Hetrick found that overtime hours in manufacturing among hourly workers has risen. However, average hours have not so much risen as hours have polarized. A greater proportion of work either fifty or more hours at the same time as a rising proportion works short hours. In addition, in 2005 Jared Bernstein and Karen Kornbluh found the rise in working hours has occurred more within families or dual-income households than among individuals. According to an article published by Daniel Hamermesh in Industrial and Labor Relations Review (2000), longer hours cannot be attributed to a steady replacement of hourly paid with salaried jobs.

Any trends in overtime work may be traced to the economics of labor demand and labor supply. Employers’ demand for longer hours is driven by their response to economic incentives and market pressures to drive down labor costs per hour. Employers will substitute hours for employees when the fixed costs of hiring, training, and employee benefits escalate. Rising hours will be reinforced if workers prefer to allocate more time toward paid work activities because of the net income effects of falling real hourly wages, rising job insecurity, or rising consumer debt. In addition, the diminished presence, weakening, and changing priorities of the labor movement has removed an institutional pressure that once leaned against rising work hours. Unionized or not, overtime for hourly workers has often become a rationed privilege, where the legal or contracted pay premium has become an incentive to supply more hours of labor.

Nevertheless, the repercussions of overtime—usually unpaid hours for salaried workers—take its toll not only on individuals, but also on families, workplaces, and society. Studies confirm that overtime work is a dual-edged sword, providing additional income but also adverse repercussions due to the heightened risk of injury, illness, accident, and work-family time conflict, via fatigue and stress. Such risks are often magnified when overtime is imposed rather than voluntary. Early-twenty-first-century controversies in research involve the appropriate degree of annual averaging of work hours and the extent to which curbing overtime would spur employment. Policy propos-
als that attempt to alter the framework for regulating or enforcing overtime laws, in the United States and elsewhere, become controversial. This includes the scope of which jobs are to be covered by the FLSA's overtime pay premium, limiting mandatory overtime work, and whether compensation for overtime hours should be in the form of future promised compensatory time off rather than immediate pay.

PACIFISM

The term pacifism is a neologism that was coined in the early twentieth century. It was invented by the French notary Emile Arnaud, who used it in a newspaper article in 1901. According to Karl Holl, Arnaud wanted to stress the peculiar determination and common ideological orientation of those who were not only "peaceful" or "peace-makers," but "pacifists," and he therefore formed an "ism" similar to other political currents, such as socialism or liberalism. The new concept was meant to incorporate all previous goals of the bourgeois peace movement—including arbitration, disarmament, and a European confederation—under a new label. The term was also meant to suggest parity with other political movements, and to play up the theoretical pretense of this current. The last point was particularly important for central European pacifists such as Alfred Hermann Fried. Older terms such as peace movement, mouvement pacifique, or Friedensbewegung were not fully displaced by the neologism.

It has been suggested that an analytical distinction be made between pacifism, a position that rejects both war and support for war, and "pacificism," which aims to reform the international system and rejects aggressive wars, but which also underlines the justification of military defensive against a foreign aggressor (Ceadel 1987, p. 5). This distinction is problematic, however, because it disregards most of the early proponents of pacifism, including most of the peace societies of nineteenth-century Europe. These groups were sympathetic to the idea of national defensive warfare and promoted what the historian Sandi Cooper has called a "patriotic pacifism" (Cooper 1991). The distinction also focuses too much on the ideological ramifications of peace activism, thereby neglecting forms of agitation and group sociability as key angles for a historical interpretation.

The strength of pacifist groups in the period from 1810 to 1945 depended particularly on their ability to lay claim to a respected position within the political culture of the respective countries. The capacity for pacifist mobilization was strongest in countries with a substantial pietist community and related cultural traditions, such as the United Kingdom, Germany, Switzerland, the Netherlands, and the Scandinavian countries. The pietist mentality, with its moralistic language and its commitment to salvation for a sinful world (based on the consciousness of the individual), fed into the dominant semantic patterns of pacifist activism and its often intense moral dichotomies. Even in the predominantly Catholic country of France, most of the founding members of the Association de la paix par le droit (ADP, Association for Peace through Law) in 1887 were Huguenots and members of the Reformed Church (Ingram 1991, p. 27).

HISTORY

Religious motives (particularly from the historic peace churches of the Quakers and Mennonites in England and the United States) engendered the first peace societies in New York (1815) and London (1816), while philanthropic motives led to similar societies in Paris (1821) and...
In both Europe and the United States, nineteenth-century pacifism relied on a homogeneous stratum of middle-class supporters and their characteristic patterns of sociability and associational life. International contacts between peace activists intensified in the last quarter of the nineteenth century, and these contacts were institutionalized through the International Peace Bureau in Bern, Switzerland, founded in 1892. The outbreak of war in August 1914 betrayed pacifist hopes that a growing network of international relations would prevent war. It also compromised most bourgeois pacifists, who demonstrated their readiness to support a national war effort. In a response to this perceived moral bankruptcy of “patriotic pacifism,” pacifist organizations with a more radical approach emerged in various countries, including the Union for Democratic Control in the United Kingdom and the Bund Neues Vaterland (New Fatherland League) in Germany.

European pacifism in the 1920s and early 1930s was characterized by the coexistence of a liberal current on the one hand and a more radical or integral current on the other. The former was represented by the ADP in France, the League of Nations Union in Britain, and the liberal current in the Deutsche Friedensgesellschaft (German Peace Society, DFG). The latter was exemplified by groups such as the Ligue internationale des combattants de la paix (LICP) in France and the Peace Pledge Union (PPU), founded by the Anglican clergyman Dick Sheppard, in the United Kingdom. Toward the end of the 1920s, ideological conflicts between the two wings hardened, and sectarianism and organizational fragmentation prevailed. This was due not only to individual idiosyncrasies and the growing militancy of many radical pacifists. It also reflected the fact that the political and cultural cleavages between liberal dignitaries, with their characteristic patterns of sociability, and radical democrats, socialists, and anarchists, which represented a broader cross section of society, could no longer be reconciled.

The Italian invasion of Abyssinia in 1935, the militarization of the Rhineland by the Nazi government in 1936, and particularly the Spanish Civil War from 1936 to 1939 undermined the moral and political foundations of European pacifism. The tendency of the PPU to grant concessions to Nazi Germany, along with the apparent failure of the British appeasement policy, compromised its moral grounds. Italian and German military intervention against the Spanish Republic called for a revocation of a principled nonviolent stance, as powerful critics such as George Orwell argued. And with the Nazi seizure of power in 1933, German pacifists were forced into exile or became subject to police persecution. Soon, pacifists in countries such as Norway or France would have to decide whether they would participate in violent resistance against the German occupation.

In both historical and sociological perspective, pacifism ceased to exist as a major political current after World War II. In terms of sociability and mobilization, the permanent but small associations of middle-class dignitaries were transformed into the more fluctuating single-issue campaigns of peace movements, with their ability to attract highly volatile mass support. In terms of ideology and the support of nonviolent methods, some of the former pacifist impetus shifted toward an engagement in human rights campaigning. Yet since 1945 a strictly nonviolent, pacifist orientation has still consistently been displayed by organizations such as the War Resisters’ International (WRI). Since its foundation in 1921, the WRI has promoted nonviolent direct action and supported conscientious objectors. It has emerged as a major transnational network of radical pacifists, with branches in various European countries, the United States, and other parts of the world.

PALESTINE LIBERATION ORGANIZATION (PLO)

The Palestine Liberation Organization (PLO) is an umbrella political organization founded in 1964 to deal with the problems of the Palestinian Arab refugees. The 1947 United Nations Partition Plan for Palestine (UN General Assembly Resolution 181 of November 29, 1947) had divided the ex-British mandate territory of Palestine into a Jewish state and an Arab-Palestinian state, with the Greater Jerusalem area, including Bethlehem, placed under international administration. But the first Arab-Israeli war (1948–1949) led to a three-way partition of Palestine and the problem of the so-called occupied Palestinian territories. Egypt took the Gaza Strip, the kingdom of Transjordan (later Jordan) took the West Bank (of the River Jordan), and the rest of Palestine was incorporated into the newly formed State of Israel, prompting the exodus of hundreds of thousands of Palestinian Arabs who were dispersed to refugee camps all over the Arab world. The PLO emerged from the angry despair of the homeless and impoverished Palestinian refugees and their desire to establish an independent Palestinian state in the “occupied territories.”

The PLO is governed by a legislative body called the Palestinian National Council (PNC), which elects an executive committee to assume leadership of the organization between its sessions. The PNC meets every two years and passes resolutions by a simple majority with a two-thirds quorum. The first PNC, composed of 389 nominated representatives from Palestinian diaspora communities in Jordan, Gaza, Egypt, Syria, Lebanon, Kuwait, Iraq, Qatar, Libya, and Algeria, met in East Jerusalem, Jordan, on May 29, 1964, and adopted the Palestinian National Covenant (Palestine’s constitutional charter). It established the PLO as the political voice of the Palestinian people and elected Ahmad Al-Shuqeiry (1908–1980) as the first chairman of the PLO Executive Committee.

Fatah, an Egyptian-backed guerrilla movement led by Yasser Arafat (1929–2004), joined the PLO in 1968. It was followed by other Palestinian guerrilla groups (fedayeen) such as the pro-Syrian As Saïqa, the Marxist-oriented Popular Front for the Liberation of Palestine (PFLP), and the leftist Democratic Front for the Liberation of Palestine (DFLP), among others. The PLO’s military wing, the Palestine Liberation Army (PLA), began staging acts of guerrilla warfare against military and civilian targets inside Israel, as well as Jewish targets in third countries; the Israeli government has branded these acts “terrorism.” Arafat became PLO leader in 1969 and declared himself the only legitimate spokesman for the Palestinian people. For much of its history, the PLO regarded Israel as an illegitimate foreign presence in Palestine, because neither the local Palestinian Arabs nor any neighboring Arab country have ever agreed to the creation of a Jewish state in their midst. The PLO leadership has accused Israel of illegally occupying the Arab lands in Palestine, especially the Gaza Strip and the West Bank, including East Jerusalem, which were captured by Israel during the Six-Day War of June 1967. The PLO has also insisted on the “right to return” to their ancestral homes for hundreds of thousands of Palestinian refugees (and their descendants) who were forced into exile in 1948.

The PLO was expelled from its guerrilla bases in Jordan after a bloody confrontation with the army of Jordanian King Hussein I (1935–1999) in September 1970 (which became known as “Black September” because as many as 3,400 Palestinians were killed in the conflict). The defeated PLO relocated most of its fighting force to refugee camps in Lebanon and Syria. In 1974 the Arab League proclaimed the PLO the “sole legitimate representative” of the Palestinians, with Jordan and Egypt giving up their claims to the West Bank and Gaza, respectively. In the same year, Arafat called for a democratic, secular Palestinian state, and the United Nations recognized the PLO as the government-in-exile responsible for all Palestinian affairs, according it the status of a permanent observer to the UN. Since then, more than 100 non-Arab states have also extended diplomatic recognition to the PLO as the legitimate representative of the Palestinian people. The PLO was granted full membership in the Arab League in 1976.

The PLO became embroiled in the first phase of the bloody Lebanese Civil War (1975–1977), but suffered defeat at the hands of the Syrian army, which in 1976 invaded Lebanon in support of the Christian-dominated government in Beirut. Arafat rejected the Camp David Accords of 1977 and accused Egyptian president Anwar Al Sadat (1918–1981) of betraying the Palestinian people and all other Arab nations, but at the same time called for diplomacy to resolve the Palestinian problem. The PLO suffered another setback in 1982 when the Israeli invasion of Lebanon forced some 8,500 of its fighters to leave their stronghold in West Beirut and resettle in other Arab countries, such as Tunisia and Syria. In 1985 the Israeli air force bombed the PLO headquarters in Tunisia, inflicting significant losses of life, but missing Arafat. The PLO was caught by surprise by the first Palestinian intifada (1987–1993), and while it was trying to help and direct the anti-Israeli uprising from abroad, the local radical Islamic groups Hamas and Islamic Jihad challenged its leadership position within the occupied territories. The PLO emerged from the angry despair of the homeless and impoverished Palestinian refugees and their desire to establish an independent Palestinian state in the “occupied territories.”

The PLO is governed by a legislative body called the Palestinian National Council (PNC), which elects an executive committee to assume leadership of the organization between its sessions. The PNC meets every two years and passes resolutions by a simple majority with a two-thirds quorum. The first PNC, composed of 389 nominated representatives from Palestinian diaspora communities in Jordan, Gaza, Egypt, Syria, Lebanon, Kuwait, Iraq, Qatar, Libya, and Algeria, met in East Jerusalem, Jordan, on May 29, 1964, and adopted the Palestinian National Covenant (Palestine’s constitutional charter). It established the PLO as the political voice of the Palestinian people and elected Ahmad Al-Shuqeiry (1908–1980) as the first chairman of the PLO Executive Committee.

Fatah, an Egyptian-backed guerrilla movement led by Yasser Arafat (1929–2004), joined the PLO in 1968. It was followed by other Palestinian guerrilla groups (fedayeen) such as the pro-Syrian As Saïqa, the Marxist-oriented Popular Front for the Liberation of Palestine (PFLP), and the leftist Democratic Front for the Liberation of Palestine (DFLP), among others. The PLO’s military wing, the Palestine Liberation Army (PLA), began staging acts of guerrilla warfare against military and civilian targets inside Israel, as well as Jewish targets in third countries; the Israeli government has branded these acts “terrorism.” Arafat became PLO leader in 1969 and declared himself the only legitimate spokesman for the Palestinian people. For much of its history, the PLO regarded Israel as an illegitimate foreign presence in Palestine, because neither the local Palestinian Arabs nor any neighboring Arab country have ever agreed to the creation of a Jewish state in their midst. The PLO leadership has accused Israel of illegally occupying the Arab lands in Palestine, especially the Gaza Strip and the West Bank, including East Jerusalem, which were captured by Israel during the Six-Day War of June 1967. The PLO has also insisted on the “right to return” to their ancestral homes for hundreds of thousands of Palestinian refugees (and their descendants) who were forced into exile in 1948.

The PLO was expelled from its guerrilla bases in Jordan after a bloody confrontation with the army of Jordanian King Hussein I (1935–1999) in September 1970 (which became known as “Black September” because as many as 3,400 Palestinians were killed in the conflict). The defeated PLO relocated most of its fighting force to refugee camps in Lebanon and Syria. In 1974 the Arab League proclaimed the PLO the “sole legitimate representative” of the Palestinians, with Jordan and Egypt giving up their claims to the West Bank and Gaza, respectively. In the same year, Arafat called for a democratic, secular Palestinian state, and the United Nations recognized the PLO as the government-in-exile responsible for all Palestinian affairs, according it the status of a permanent observer to the UN. Since then, more than 100 non-Arab states have also extended diplomatic recognition to the PLO as the legitimate representative of the Palestinian people. The PLO was granted full membership in the Arab League in 1976.

The PLO became embroiled in the first phase of the bloody Lebanese Civil War (1975–1977), but suffered defeat at the hands of the Syrian army, which in 1976 invaded Lebanon in support of the Christian-dominated government in Beirut. Arafat rejected the Camp David Accords of 1977 and accused Egyptian president Anwar Al Sadat (1918–1981) of betraying the Palestinian people and all other Arab nations, but at the same time called for diplomacy to resolve the Palestinian problem. The PLO suffered another setback in 1982 when the Israeli invasion of Lebanon forced some 8,500 of its fighters to leave their stronghold in West Beirut and resettle in other Arab countries, such as Tunisia and Syria. In 1985 the Israeli air force bombed the PLO headquarters in Tunisia, inflicting significant losses of life, but missing Arafat. The PLO was caught by surprise by the first Palestinian intifada (1987–1993), and while it was trying to help and direct the anti-Israeli uprising from abroad, the local radical Islamic groups Hamas and Islamic Jihad challenged its leadership position within the occupied territories. The
PLO also lost financial support from wealthy Arab Gulf states for backing Iraq during the First Gulf War (1990–1991).

With U.S. support, Israel refused to negotiate with the PLO, insisting that it would only talk to Palestinian representatives from the occupied territories, which complicated and delayed the peace process. In reaction to the intifada, the PLO unilaterally declared an independent “Arab state of Palestine” at the nineteenth PNC session held in Algiers in 1988. Arafat expressed support for a UN Security Council resolution calling for a two-state settlement on the pre-1967 borders (which had been vetoed by the United States in January 1976), with Israel and Palestine living side by side, provided that East Jerusalem became the capital of the Palestinian state and Palestinian refugees were given the right to return to their pre-1948 homes in Israel. On September 13, 1993, after months of U.S.-brokered back-channel negotiations, Arafat signed an historic peace agreement with Israel in Oslo, Norway, even though such an accommodation was vehemently opposed by radicals within the PLO’s own ranks and by irreconcilable Palestinian groups such as Hamas and Islamic Jihad. The agreement, known as the Oslo Accords, involved mutual recognition, with security guarantees to and from Israel, and the gradual introduction of Palestinian self-government and autonomy in Gaza and parts of the West Bank until a final peace settlement was signed. A year later, Arafat appointed a provisional government, the nineteen-member Palestinian Authority, to administer the areas of Palestinian self-rule. He was elected president of the Palestinian-controlled territories in 1996. The PLO convened a PNC session in Gaza in April 1996, which voted with 504 votes in favor and 54 against to recognize Israel’s right to exist.

Mahmoud Abbas (b. 1935), a moderate Fatah politician, was appointed Palestinian prime minister in 2003 in the midst of the second intifada (2000–2006). In the same year, Palestinians and Israelis agreed to new negotiations based on the U.S.-proposed “roadmap to peace,” although this failed to stop the daily violent attacks and reprisals. However, Abbas soon resigned after clashing with Arafat over control of the PLO’s security forces. Following Arafat’s death in November 2004, Abbas succeeded him as PLO leader and was elected Palestinian Authority president in January 2005.

In an unexpected blow to Abbas, Hamas swept the Palestinian parliamentary elections in January 2006 and formed a Hamas-led Palestinian Authority cabinet that promised to rid Palestinians of the rampant corruption, mismanagement of foreign aid, and endemic abuses of power under Arafat’s rule. The result was an escalating conflict between President Abbas and Palestinian prime minister Ismail Haniyeh (b. 1963) of Hamas over many issues, including Hamas’s retaliatory missile attacks on Israeli territory and Abbas’s plan to hold a referendum to force Hamas to recognize Israel. To end sporadic armed clashes between Hamas members and the Fatah-controlled security forces, a Hamas-led coalition government with the participation of several Fatah-supported ministers was formed in March 2007. But the Hamas-Fatah coalition collapsed in June 2007 when a military confrontation between the two rival groups led to Hamas’s victory and takeover of Gaza. Without the consent of the Hamas-dominated Palestinian parliament, Abbas dissolved the coalition government and appointed an emergency cabinet led by pro-Fatah prime minister Salam Fayyad (b. 1952) on June 17, 2007, signaling a newly divided Palestine ruled by the Iranian-backed Hamas in Gaza and the American-backed Fatah in the West Bank.

PALESTINIAN AUTHORITY

The establishment of the Palestinian Authority (PA) in 1994 was a culmination of a process dating back to the Madrid Conference of October 1991 when Israelis and Palestinians engaged in official direct negotiations for the first time. The Declaration of Principles (DOP), which was officially signed by Israel and the Palestinian Liberation Organization (PLO) in September 1993 in Washington, D.C., gradually led to Palestinian self-government in about 42 percent of the West Bank and the whole Gaza Strip.
THE ESTABLISHMENT OF THE PALESTINIAN AUTHORITY

The DOP, also known as the Oslo Accords, are the first sustained effort sponsored by the international community led by the United States and Russia to find a peaceful solution to the Israeli-Palestinian conflict on the basis of United Nations resolutions 242 and 338. The marginalization of the PLO after the first Gulf War and the impacts of the first intifada (a Palestinian uprising directed against Israel) on Israeli perceptions of the Palestinians made both sides more willing than ever to directly negotiate with each other. The DOP was based on the Israeli recognition of the PLO as the legitimate representative of the Palestinian people in exchange for the PLO’s recognition of the State of Israel.

The DOP envisioned the creation of Palestinian autonomous government in Gaza and the West Bank as a three-stage process in five years. The Cairo agreement between Israel and the PLO in 1994 established Palestinian self-rule in Gaza and the West Bank city of Jericho. The second stage was initiated with the signing of the “Oslo 2 Accord” in September 1995 when Palestinian self-rule was extended to the West Bank, which was divided into three zones. PA would control all civilian and security affairs in Zone A, which would cover cities populated by the Palestinians. Zone B would consist of Palestinian villages, and Israel would have final authority in external security in this zone. Zone C would include Jewish settlements, strategic roads, and sparsely populated areas (which made up 70 percent of the West Bank) and would remain under Israeli control. There were no restrictions on the further expansion of Jewish settlements in this zone. While the PA gained control of about 30 percent of the West Bank, only 3 percent of this area was in Zone A.

The Oslo Process continued with additional agreements in the 1990s. The Hebron Agreement in January 1997 divided the city of Hebron into two and resulted in the redeployment of Israeli soldiers to a smaller section of the city. In October 1998 Israel and the Palestinians signed the Wye Memorandum that called for further redeployment of the Israeli military in the West Bank and the PA to fight against terrorism against Israel. The third and final stage was originally scheduled to take place in 1999 and would have led to a peace treaty solving all core issues, such as the status of East Jerusalem, Jewish settlements, refugees, security arrangements, and water rights. While Palestinians consider East Jerusalem as the capital of their future state, Israel, which annexed East Jerusalem, refused to relinquish its sovereignty over the city. Israel and the Palestinians reasserted their commitment to the resumption of permanent status negotiations by signing the Sharm el-Sheik Memorandum in September 1999. However the outbreak of the second intifada in September 2000 ultimately derailed the process.

The creation of the PA was a major step toward the fulfillment of Palestinian national aspirations. However the PLO’s recognition of Israel and the Oslo Process did not enjoy universal approval among Palestinians. A rejectionist front that included Hamas and Islamic Jihad denounced the Oslo Process. Terrorist attacks by militant Palestinian groups and Israeli retaliations undermined the process and fueled the mutual suspicions between Israel and the Palestinians. Furthermore, the Palestinian support of diplomatic negotiations with Israel was not sustainable. The partial Israeli withdrawal from Gaza and the West Bank did not necessarily translate into independence, security, freedom of action, and economic well-being for the Palestinians. The PA was not sovereign and was highly dependent on Israeli cooperation for its survival. It had no control over its external borders, customs, airspace, water, and minerals. Israel collected the PA’s custom duties, taxed Palestinian citizens working in Israel on behalf of the PA, and remained the market for its export and the source of its imports. Foreign assistance made a substantial portion of the PA’s budget. From the Israeli perspective, the main task of the PA was the establishment of order and security in the Palestinian territories and the end of attacks against Israeli military and citizens. From the Palestinian perspective, the Oslo Process would ultimately result in the establishment of a Palestinian state in Gaza and the West Bank. By 2000 neither side achieved its goals.

1996 ELECTIONS AND THE STRUCTURE OF THE PA

The DOP specified that free and general elections should be organized in the West Bank and Gaza to enable the Palestinians to govern themselves according to democratic principles. The elections for the Palestinian legislative council (PLC) and the presidency took place in January 1996 after Israeli military withdrew from Zones A and B in December 1995. Yasser Arafat (1929–2004), who was the leader of both Fatah (the Palestinian National Liberation Movement, a branch of the PLO) and the PLO, was elected president by capturing around 88 percent of the vote. Fatah dominated the legislative council elections, which was boycotted by Hamas, by capturing a majority of the seats.

Despite having popular legitimacy, the PA was characterized by authoritarian practices. Power was personalized in the hands of Arafat who thwarted the PLC’s attempts to make him more accountable and to end his ruling by decree. While the PLC ratified the Basic Law in 1997, which was intended as an interim constitution, Arafat did not ratify it for five years. He populated senior positions mostly with comrades from Fatah who had been in exile.
Palestinian Authority

for decades at the expense of local leaders and grassroots organizations. The tension between “outsiders,” who did not participate in the intifada, and “insiders,” who had public support, fostered discontent with the PA. Public positions were distributed according to personal connections, histories, family relations, and patronage considerations. Distinction between personal and public budget blurred and the administration was beset by widespread corruption and incompetent management. The establishment of multiple layers of security forces facilitated the suppression of dissent. The PA’s intimidation of the Palestinian press contributed to the rise of self-censorship. The PA entered into strategic alliances with local notables by co-opting and assigning them positions in the administration. All these practices diminished the prospects for a vibrant civil society and eroded the rule of law.

The PA’s obligations to Israel and the Palestinian people were hardly compatible. On the one hand, Israel demanded the PA to prevent security threats to Israeli civilians and military from the areas it controlled. On the other, Palestinians expected that the establishment of the PA would stop Israeli incursions, blockades, and expansion of settlements. The PA’s performance in combating attacks against Israeli targets was not satisfactory for Israel and the latter continued its policies of retaliation and intimidation against the Palestinians. As a result both Palestinian and Israeli support for the PA diminished.

THE SECOND INTIFADA AND THE COLLAPSE OF THE OSLO PROCESS

The official deadline for conclusion of Israeli-Palestinian formal settlement negotiations passed on May 4, 1999. It appeared to all parties that the Oslo Process was reaching a dead end. In July 2000 U.S. president Bill Clinton invited Arafat and Israeli prime minister Ehud Barak to a summit at Camp David to achieve a breakthrough. However, the summit was terminated without an agreement. After the Israeli Likud leader Ariel Sharon visited the Temple Mount, sacred for both Muslims and Jews, in September 2000, Israeli Arabs and Palestinians in the West Bank rioted. Younger generation Fatah members created Tanzim, an armed wing of Fatah, and confronted the Israeli military. The Oslo Process was in shambles. The conflict escalated to a new level in April 2002 when Israel conducted “Operation Defensive Shield” and reoccupied the parts of the West Bank and Gaza it had previously withdrawn from. Arafat was surrounded in his compound in Ramallah, in the West Bank. Israel accused Arafat of igniting the intifada and sponsoring terrorism and demanded his dismissal. In the same year, Sharon who won the Israeli elections in 2001, began constructing a barrier intended to separate the Palestinian West Bank from Israel and stop suicide terrorism employed by the militant Palestinian groups. As a result of Israeli operations and blockades the PA was in crisis. Unemployment skyrocketed among the Palestinians and the economy collapsed. Meanwhile, U.S. president George W. Bush declared that he would conditionally support the establishment of a Palestinian state in June 2002. His conditions included a comprehensive reform of the PA, the replacement of Arafat, and Palestinian agreement to a ceasefire. In 2003 the PLC amended the Basic Law as part of the reform initiative. A post of prime minister was created and the number of seats in the PLC was increased from 88 to 132. Arafat appointed Mahmoud Abbas as prime minister and gave away some of his extensive powers to him in March 2003. However, Abbas resigned in October complaining about his lack of power.

THE ROAD MAP AND TRANSITION OF POWER IN THE PA

Bush’s declaration ultimately resulted in the Road Map for Peace, which was released in April 2003. The Road Map was issued by the Quartet—the United States, the European Union, Russia, and the United Nations—and was intended to end the Israeli-Palestinian conflict by 2005. It required the PA to make democratic reforms and end its support of terrorism. The conditions seemed positive for progress toward peace negotiations as two developments in 2004 abated the level of violence. In February 2004 Sharon announced that Israel would unilaterally withdraw from Gaza, and in November 2004 Arafat died. Following Arafat’s death, presidential elections were held in January 2005. Hamas boycotted the elections and Marwan Barghouti, who was a popular leader of Tanzim, retired from the race several weeks before voting was to occur. Consequently, the Fatah candidate Abbas easily won the elections with 62 percent of the votes cast. Abbas’s election to the presidency led to a thaw in relations with the United States and Israel. A month after his election, he met with Sharon and they both declared their commitment to work together to end the violence. In May Abbas visited the White House and received Bush’s support for an independent Palestine and promise of direct aid in exchange for the PA’s crackdown on terrorism. In August Israel dismantled the Jewish settlements and disengaged from Gaza.

The second Palestinian presidential and parliamentary elections were originally scheduled for 2001; however, the elections were indefinitely delayed after the outbreak of violence. After the death of Arafat in November 2004, Palestinian factions met in Cairo, Egypt, in March 2005 to discuss how to replace him. Fatah consented to have elections, and Hamas agreed to a ceasefire with Israel. After the adoption of a new electoral system the same month, the parliamentary elections eventually
took place in January 2006. This time Hamas did not boycott the elections and defeated Fatah by capitalizing on public discontent with the PA’s past ten-year performance. Hamas captured 74 of the 132 seats to Fatah’s 45 seats in the PLC. Hamas formed a new cabinet in March and Ismail Haniya became the prime minister. The relationship between Hamas and Fatah remained tense and skirmishes took place between militants in October 2006.

Hamas, which does not officially recognize Israel, isolated the PA in the international arena and ended the thaw between the PA and Israel. The U.S. administration refused to deal with Hamas until it renounced its terrorist tactics and recognized Israel’s right to existence. Both the United States and the European Union cut all aid to the PA, and Israel declined to hand over tax receipts it had collected on behalf of the PA. As a result the PA was unable to pay the salaries of its civil servants, which had disastrous consequences for Palestinian society. In June 2006 Israeli military reentered Gaza following an attack that killed two Israeli soldiers and abducted one. Israel detained Hamas members including ministers and PLC representatives. This most recent conflict further undermined the prospects for diplomatic negotiations between the PA and Israel.

PALESTINIAN DIASPORA

There is an increasing literature that describes as diasporic the twentieth-century dispersion of the Palestinian people from their historical homeland in the Middle East. However, the question arises whether celebrating the hybridity and the challenge to notions of nation-state and the dominant culture inherent in diaspora cultures does not detract from legitimate political claims to the homeland that was lost. This is particularly obvious in the case of the Palestinians. Thus, the literature on Palestinian diaspora communities and their experiences of dispersal and uprootedness demonstrates some unease in using the term diaspora precisely because it implies the possibility of permanence and the denial of return. The terms exile and refugee are more prominent in the discourses on Palestinians and in the Palestinians’ own usage. Both terms put a much stronger emphasis on the forced nature of the dispersal and the intent to return to the homeland, however symbolic or realistically impossible such a return may be. Using the term diaspora for the Palestinian experience can, on the other hand, allow comparison with other communities in order to contextualize the Palestinian experience in a global political, social, and cultural framework.

The term diaspora has historically been linked exclusively to the experience of the Jewish people and their dispersal from the “promised land.” The Greek word means “the scattering or sowing of seeds.” More emotionally charged for Jews than diaspora is exile, linked to suffering, displacement, and physical distance from the homeland, while the term diaspora can connote the potentially beneficial scattering of seeds and thus the possibility of growth and improvement.

It is only in the later twentieth century that the term diaspora came to be used more widely for other groups of migrants with a history of dispersal and global networks of communities. In this more recent usage, it has come to denote a specific field of migration studies, namely diaspora studies. Within this field the exact meaning of the term has been subject to debate concerning the criteria that define a diaspora. The emerging consensus requires the following features: interconnected communities in at least two places in the world; a shared collective attachment to the homeland; and a sense of collective history of displacement or expansion, a common identity combined with a more or less uneasy relationship with the host societies. Some scholars insist that the cause of the dispersal has to be related to force or to another form of trauma; others argue that this would limit the definition too much. Arguably, many of these characteristics can be found in the history and present situation of the Palestinian people.
Palestinian migration from the area of historical Palestine can be traced to the beginning of the twentieth century. Palestine had been one of the remote provinces of the Ottoman Empire, economically underdeveloped but politically touched by ideas of Arab nationalism, which resulted in the emergence of a sense of Palestinian identity parallel and overlapping with other local identities and awareness of being Ottoman subjects. Between the world wars and after the collapse of the Ottoman Empire, Arabs emigrated from Palestine to Europe and the Americas in search of better employment and fortune, or they sought higher education after being introduced to Western ideas and education through missionary schools.

Regional migration, as well as economic exchange and trade between Syria, Lebanon, Palestine, and Jordan, was unrestricted, as the area was considered the unified region of Greater Syria. The first major event that caused a larger emigration movement was the 1936–1939 Arab revolt. In their protest against the British mandate and the increasing numbers of Jewish immigrants (supported by Britain), Palestinians were involved in armed clashes and subject to British persecution, while the economic situation deteriorated further and led especially younger males to seek employment, education, and fortune outside of the Middle East.

The war of 1947 to 1948 and its result, the creation of the State of Israel, simultaneously experienced as An-Nakba (the catastrophe) for Palestinians, created the Palestinian refugee problem, turning approximately 750,000 Palestinians (75 percent of the Palestinian Arab population) into refugees. Many of them fled their villages in fear of massacres and battles; others were forcibly evicted or barred from returning to their homes. Ultimately, most of them were prevented from returning to the territory that became the State of Israel. They took refuge in the West Bank (which was controlled by Jordan during the war and declared Jordanian territory in 1950) or in the Gaza Strip under Egyptian control. Many others fled to Lebanon and Syria.

In 1949, in response to the desperate humanitarian situation and the growing needs of the Palestinian refugees, the United Nations founded the UN Relief and Works Agency (UNRWA) with the mandate to administer aid to the Palestinian refugees in Jordan, Syria, Lebanon, the West Bank, and Gaza. Refugee camps under UNRWA control were set up, for the most part physically separating Palestinian refugees from the surrounding host societies. Arab countries and Palestinians shared political agreement in their refusal to permanently resettle Palestinians in any country other than Palestine.

During the 1950s and 1960s Palestinians left Israel, as well as the West Bank and Gaza, in search of employment. The economic situation was extremely depressed, further complicated by political oppression in Israel, where Arab towns and villages stayed under military control. Palestinians also went from Gaza to Egypt for education, while others sought employment in the Gulf states, where the discovery of oil demanded skilled laborers and professionals. On the political level, the Palestine Liberation Organization (PLO) was founded in 1964 by Palestinians outside of Palestine, in the diaspora.

The Six-Day War of 1967, in which Israel occupied the West Bank, East Jerusalem, and Gaza, turned many Palestinians into refugees for the second time. An estimated 250,000 West Bank residents and 75,000 residents of Gaza were driven from their homes between June 1967 and December 1968. They fled to Jordan, Egypt, Lebanon, and Syria, often moving several times. The rate of emigration slowed between 1969 and 1974 when a strong sense of holding on to the land based on the ideology of sumud (steadfastness) emerged and the Palestinian liberation movement, which had consolidated its organizational structure outside of Palestine, instilled a renewed sense of political pride and Palestinian identity.

Relatively steady numbers of Palestinians left the Occupied Palestinian Territories from the mid-1970s onward. They responded to Israeli policies of political and cultural oppression and land confiscation. Family and chain migration, as well as the immigration policies of potential host countries, became important factors for Palestinian patterns of temporary settlement in countries throughout the world. Major political events, such as the first Intifada (from 1987) and the second Intifada (from 2000), and their negative effects on safety, the political climate, the economy, and education, forced more Palestinians to leave the Occupied Territories and prevented many others from returning.

Palestinians living in Arab countries, however, developed their own patterns of migration, closely linked to political developments inside and outside the region. On one level, such population movement was caused by changes in the relationship between Arab host governments and the Palestinian leadership. In addition, PLO cadres and their families followed the PLO leadership to various Arab countries or were sent to other countries for organizational purposes.

At other times, Palestinians in Arab countries were caught up in larger political and military conflicts, such as the Lebanese Civil War (1975–1990) and the first Gulf War (1991). The civil war in Lebanon and the forced removal of the PLO and its military units from Lebanon in 1982 after the Israeli invasion was a major cause of migration. During the war, Palestinians who sought safety...
Palestinian Diaspora

and wanted to escape the volatile situation were accepted by Western countries as refugees or asylum seekers. In the wake of the 1982 events, PLO officials, their staffs, and their families left for Tunisia, where the PLO had reached an agreement with the government to temporarily establish its headquarters.

The Gulf War of 1991 resulted in the expulsion of a large number of Palestinians and their families from Kuwait, mainly as punishment for the Palestinian support for Iraq during the war. Many attempted to settle into a difficult life in Jordan after losing their livelihood and savings in Kuwait. Some held the necessary documents to return to the Occupied Territories, and others sought a new life elsewhere in the world.

The fall of Iraqi president Saddam Hussein in 2003 and subsequent developments in Iraq have contributed to the deterioration of the situation of Palestinians in Iraq who were politically favored by the Iraqi regime. They have experienced severe hardships and marginalization, and many have reportedly attempted to leave Iraq permanently.

PALESTINIAN DIASPORA COMMUNITIES

In 1947 the Arab population of historical Palestine numbered approximately 1.3 million people. In 2000 estimates of the number of Palestinians in the world ranged from 7.7 to 9 million. In the absence of a Palestinian state to issue passports, Palestinians in Palestine and the diaspora carry refugee travel documents or, where available, passports of current or past host countries. Thus reliable data on Palestinian demographics is scarce. Nevertheless, demographics play an important role in the political discourse on the Palestinian refugee problem and its possible solutions, and thus carry tremendous symbolic weight.

Four main groups of Palestinians can be distinguished according to location: those living in Israel, in the West Bank and Gaza, in Arab countries, and in Western countries. The reason that some of those living in the territory of historical Palestine are included in this overview is the fact that many who were internally displaced during the wars perceive their lives as shaped by a sense of inner diaspora, a temporal and special dislocation from their place of origin. This is a sentiment that should not be discounted and that has shaped various expressions of Palestinian national and cultural identity.

The Palestinians inside Israel number less than one million people and constitute approximately 20 percent of the total population of Israel. A significant number of the Palestinians in Israel are internally displaced and consider themselves internal refugees. Many of them have repeatedly attempted to return to their villages or resettle in close proximity to their place of origin; they live in unrec-ognized villages without access to Israeli health care, education, or social welfare services.

Palestinians in the West Bank and Gaza are divided into refugees and nonrefugees. In June 2005 the total refugee population of the West Bank (registered with UNRWA) was 690,988 with 26 percent (or 182,191) living in nineteen official refugee camps. In the Gaza Strip, UNRWA offered assistance to 969,588 refugees, 49 percent of whom lived in the eight official refugee camps. The number of refugees who need UNRWA assistance has dramatically increased since the beginning of the second Intifada, which led to the Israeli reinvasion of Palestinian territories, economic isolation, and political violence. Since 2000, unprecedented numbers of Palestinian refugees in the West Bank and Gaza have been pushed into poverty.

The largest of the Palestinian diaspora communities is situated in Jordan and numbers approximately 2.6 million. UNRWA reported 1,795,326 registered refugees in Jordan as of June 2005, 16 percent of whom lived in the ten official refugee camps. They are refugees from both the 1948 and 1967 wars and their descendants. A significant number of Palestinians in Jordan carry Jordanian passports, have the right to vote and hold office, enjoy full rights to public services such as higher education, and can work in the government sector. The legal, economic, and social situation of Palestinians in Jordan can be considered far better than in other countries, and some scholars even speak of a virtual merge of Palestinian and Jordanian identity. The Palestinians in Jordan are widely expected to stay in Jordan, even if the right of return may be achieved during future negotiations. Generally, it is assumed that return to a Palestinian state established in the West Bank and Gaza will be a more likely option for the 1948 refugees, while many of the 1948 refugees insist on the literal right of return to homes and villages now in Israel.

The number of Palestinians in Lebanon is widely debated and the only numbers available are limited to registered refugees (401,071) and the camp population (53%). Palestinians in Lebanon face the harshest socioeconomic conditions: their Lebanese travel documents are not recognized by most countries in the world, and they must obtain work and travel permits issued by the Lebanese authorities and are not allowed to work in the public sector and a long list of other professions. Changes in existing laws are closely linked to Lebanese domestic politics. Lebanon has with very few exceptions rejected any permanent settlement or naturalization of Palestinian refugees.

The exact number of Palestinians in Syria is unknown, but 426,919 Palestinians are registered as refugees, 27 percent of whom live in the ten UNRWA administered camps. Most refugees enjoy rights similar to
Palestinian Diaspora

those of Syrian citizens, but they are not allowed to vote, hold office, or carry Syrian passports. The travel documents issued by the Syrian government are not recognized by most states.

Palestinian refugees living in other countries of the Arab world, such as Saudi Arabia, the Gulf states, Libya, Egypt, and Iraq, are not assisted by UNRWA. Many of these Palestinians are work migrants who relocated after leaving their initial country of refuge in hope of finding better education and employment.

Palestinians in Western countries are divided into European communities and those in the Americas. The estimated numbers vary widely, but less than 6 percent of the Palestinian people live in Western diaspora communities. Many countries, such as the United States, Canada, and Australia, have, because of their status as immigration countries, over the years provided Palestinians with work and residency permits and also citizenship. Others have been accepted as refugees and asylum seekers. European countries tend to accept refugees at times of acute crises, but do not generally favor integration or naturalization of refugees.

PALESTINIAN DIASPORIC IDENTITIES AND CULTURES

A distinct feature of diaspora communities is a sense of collective identity, often linked to the events surrounding the loss of the homeland and the hardships of living separated from its territory and culture. The Palestinian diaspora is characterized by strong intercommunity networks on many levels, such as family ties, global communication, frequent migratory moves, organizational structures, and cultural exchange. These connections facilitate the preservation and negotiation of Palestinian national identities.

On one hand, scholars celebrate the emergence of new hybrid intellectual and cultural dimensions of diaspora communities. Palestinian communities have both features. Case studies of Palestinian diaspora communities in different parts of the world indicate that the more Palestinians are allowed to integrate into a host society on political, social, economic, and cultural levels, the more their Palestinian identity becomes part of a hyphenated set of identities. On the other hand, many Palestinian refugees in Lebanon or Iraq have no other identities to choose from; thus they remain in a sense more strongly Palestinian. The same correlation can be detected for integration and return wishes. The right of return is subject to heated political debate among Palestinians and internationally, and will have to be resolved as part of a final settlement of the Palestinian-Israeli conflict.

Discussion of the Palestinian diaspora is not complete without mentioning the importance of Palestinian cultural and intellectual production throughout the world and the significance of commemorating the events (in particular the 1948 war) that led to the expulsion of the Palestinians from their homeland. In the absence of national museums, school textbooks, and a state, these collective memories have been shaped by memoirs, oral history, and artistic expression. Palestinian writers, visual artists, musicians, and poets have contributed to Palestinian national culture and the cultures of their respective host countries. Palestinian intellectuals and scholars have not only shaped or challenged the field of Palestine studies but have also contributed to many areas of the social and natural sciences without denying their Palestinian diasporic identities. Such identities are by definition in flux, in a constant state of redefinition and adjustment, and one can argue that future generations of Palestinians will have to renegotiate how, where, and to what extent they want to be part of the Palestinian diaspora.

BIBLIOGRAPHY

PALESTINIANS

Historically, the term “Palestinian” has been associated with the inhabitants of the south of ancient Syria west of the Jordan River between Lebanon and Sinai. The name “Palestinian” is related to the “Philistines,” an Indo-European group that invaded the southern coast of ancient Syria from the sea in the fourteenth century BCE. The Palestinians, however, are descendants of the Canaanites, a Semitic group that migrated from the Arabian Peninsula between 3000 and 2500 BCE and settled the coastal areas of Palestine. The Arabic language and Islamic religion spread among the Palestinians with the Arab migrations from the Arabian Peninsula between 630 and 650 CE. Throughout four hundred years of Muslim Ottoman rule, Palestinians maintained an Arab identity and included Muslim, Christian, and Jewish communities. At the turn of the twentieth century, the Palestinian population was composed of a Muslim Sunni majority and minority populations of Christians (10 percent) and Jews (less than 5 percent).

After World War I (1914–1918), the Palestinians were provisionally recognized as independent under a British mandate that was supposed to provide advice and maintain their status quo until self-rule. The British, however, began to resettle European Jews in Palestine as a way of supporting the Zionist solution to the Jewish question created by the anti-Semitism of Europe. The increase in the European Jewish population from 4.8 percent in 1882 to 28 percent in 1936 created economic hardships for the indigenous population because the lands purchased were in the arable, coastal, and urban centers of Palestine. Moreover, the uneven economic policies of the British that favored the Jewish sector increased Palestinian unemployment, rural outmigrations, landlessness, and thus a cheap labor force. Palestinian discontent culminated in a general strike and protests between 1936 and 1939, which were brutally suppressed by the British army and the Jewish militia.

Palestinian lives have been shaped since mid-twentieth century by two main events, their repercussions, and the attempted solutions: Al Nakba (Arabic for “the catastrophe”) of 1948, which marked Palestinian dispossession and exile coinciding with the establishment of the Israeli state; and Al Naksa (Arabic for “the tragedy”) of 1967, which marked the beginning of the Israeli occupation in the West Bank, the Gaza Strip, and East Jerusalem. Al Nakba caused the exodus of 750,000 Palestinians from the land on which the state of Israel was established into the nearby Arab countries of Jordan, Lebanon, and Syria, as well as into the West Bank and the Gaza Strip; and Al Naksa created an additional 350,000 refugees who fled to Jordan, of whom 15,000 were allowed to return. The indigenous Palestinian population that remained on the land under Israeli control was put under military rule until 1966 and was later incorporated into Israeli society as a minority with citizenship but not equality.

After 1948 Palestinian society emerged divided between the West Bank, a kidney-shaped area of approximately 2,270 square miles whose population doubled with the arrival of refugees, and the Gaza Strip, a tiny strip of land of approximately 140 square miles absorbing a refugee population that outnumbered its inhabitants. Between 1948 and 1967, the Palestinians in the West Bank, annexed then by Jordan, could get Jordanian passports listing their citizenship as Jordanian, while the Palestinians in Gaza, under Egyptian rule, were given Egyptian travel documents listing their nationality as undetermined.

The Palestinians in both the West Bank and the Gaza Strip were united after 1967 through their status as occupied subjects sharing a history under Israeli occupation while struggling against its oppressive conditions. The contention included a guerrilla resistance in the first couple of years of occupation in the refugee camps of Gaza. It was suppressed when the camps were subjected to martial law. Sporadic protests took place in the 1970s and 1980s, a mass uprising took place in 1987, and a second uprising began in 2000.

Under occupation, all aspects of Palestinian life were subject to the Israeli military authorities’ approval, from economic activity to the right of movement, and monitored through a hierarchically ordered color-coded identity card system—to be carried at all times—differentiating Palestinian residents of East Jerusalem (blue), the West Bank (orange), and the Gaza Strip (red). The Palestinians of East Jerusalem, which was annexed by Israel after the 1967 war while remaining integral to the West Bank, were assigned the status of residents, situating them hierarchically above occupied subjects but lower than citizens. Nonetheless, the mid-1990s uncovered their shaky status when the Israeli government demanded that East Jerusalemites prove that the center of their activities continued to revolve around the city if they wanted to keep their residency rights. The residency status of close to two thousand East Jerusalemites was revoked.

The Palestinian economy, underdeveloped on the eve of the 1967 war, deteriorated under the Israeli occupation policies of control of mobility of Palestinian labor and commodities and confiscation of land for building and expanding Israeli Jewish settlements in the occupied territories. By 1993, a survey of living conditions found that Palestinian households in the territories are mostly dependent on wage labor. Moreover, Palestinians preferred to work in Israel because of higher wages even as they are paid less than the average wages of the Jewish workers. Under a general exit system in 1967, Palestinians
could cross the border to work as day laborers but were not allowed to stay after sunset. Thus, Palestinian chances for making a living in the territories largely have depended on Israeli border policies since 1967.

Peace negotiations between Palestinians and Israelis to end the occupation started in 1993 yet coincided with Israel closing its border and imposing a permit policy restricting Palestinian movement with repercussions for Palestinian livelihood. Although the peace process brought a Palestinian National Authority to Gaza and Jericho and redeployed the Israeli military from main Palestinian towns, it did not end Israeli control. Israel retained 59 percent of the West Bank lands and 20 percent of the Gaza Strip, and maintained security control over most of the West Bank. In the years following the arrival of the Palestinian Authority to the territories in 1994, Palestinians faced more mobility restrictions—between Gaza, the West Bank, and East Jerusalem, within the West Bank. Additionally, the construction of a wall between the West Bank and Israel has had significant consequences for Palestinian social life.

PAN-AFRICAN CONGRESSES

Pan-African congresses is the name given to seven international meetings planned by W. E. B. Du Bois between 1919 and 1929, of which four actually materialized, and another meeting in 1945 in which he participated only peripherally in planning and organizing, but over which he presided. At the 1945 congress, he called for another to take place nine years later. This materialized only in 1974, after his death. Another congress took place in 1994, with another proposed a few years later.

THE ORIGIN OF THE TERM PAN-AFRICAN

Pan-African was coined, it is claimed, by the Trinidadian lawyer Henry Sylvester Williams in an 1899 letter concerning the Pan-African Conference of 1900. It appears, however, that Du Bois had a much greater claim to the term. It is plausibly derived from the Pan-Slav, Pan-German, and Pan-American movements, of which the most influential for residents of the Western Hemisphere would logically be the Pan-American movement.

Du Bois is the only major participant to link explicitly in print all four of these pan-movements. In 1888 he gave as his valedictory address at Fisk University a speech titled “Bismarck”; Du Bois said that Otto von Bismarck, the German chancellor, was his hero because of his feat in organizing the reunification of Germany. While at the University of Berlin from 1892 to 1894, Du Bois wrote a PhD dissertation in economics under the Pan-German Gustav von Schmoller. Heinrich von Treitschke, whom Du Bois described as a “fire-eating Pan-German,” was the philosophical leader of the Pan-German League, and discussed its tenets in class. During this period, Du Bois also traveled to Pan-Slav centers in Prague, Bohemia; “the borders of Russia”; and Krakow, Poland. The movement held a demonstration in Prague in 1898. Du Bois wrote of these travels in his letters from Europe to the New York Age, a weekly newspaper, from 1892 to 1894 and in his 1940 and 1968 autobiographies. Also in his autobiographies, Du Bois wrote of James G. Blaine, the U.S. secretary of state in 1881 and from 1889 to 1892, and the architect of the U.S. government’s Pan-American policy. Thus, Du Bois mentioned in published writings the individuals or sites associated with all three prior pan-movements. The European pan-movements differed from the American movement, which was based on the unity of independent territorial states only, without regard to language or ethnicity.

By contrast with Du Bois, Williams used the term Pan-African only in one unpublished letter and in the documents promoting the 1900 conference. For him, there is no indication of the provenience of the term.

Three other aspects of Pan-African conferences/congresses are considered in this entry: (1) the participants; (2) the public resolutions and other documents; and (3) the organizations established to continue the movement.

CONFERENCE PARTICIPANTS

It should be noted that continuity from congress to congress was guaranteed, because each of the meetings from
1919 to 1974 was organized by participants from previous meetings. Du Bois, as stated, participated in every meeting between 1900 and 1945. C. L. R. James, Amy Ashwood Garvey, T. Ras Makonnen, and Adam Clayton Powell Jr. provided direct links between the 1945 and 1974 congresses. However, the Seventh Pan-African Congress, held in Kampala, Uganda, in 1994, had no participants from previous congresses.

PUBLIC RESOLUTIONS, MANIFESTOS, AND MESSAGES
The documents produced by the Pan-African meetings through 1945 include:

- 1900: “Address to the Nations of the World”
- 1919: the Du Bois “Memorandum” and the “Resolutions of the Pan-African Congress”
- 1921: the “Manifesto of the Second Pan-African Congress” and “The Pan-African Association Declared the 8 December 1921 Statutes”
- 1923: “Resolutions”
- 1927: “Announcement of the Fourth Pan-African Congress,” “About the Pan-African Congress,” and a press release on the resolutions
- 1945: a “Memorandum to the U.N.O.” and “Resolutions”

Du Bois wrote most of these documents. Several themes in them stand out. Perhaps most striking is his use of the term Africa for the Africans, which appeared from 1921 to 1927. Second, Du Bois always began with a demand for self-government in the African colonies. Third, with the exception of 1919, he always addressed the plight of those of African descent in the Americas, and elsewhere in the African diaspora. Brazil, however, was addressed only in 1921 and 1923. In 1927 his horizons extended beyond Africa to China and India. The 1945 documents contained no reference to the plight of the African diaspora, but in his own speech, Du Bois did stress that theme repeatedly. Fourth, he always spoke of the plight of black labor, and of black access to land and capital.

The “General Declaration” of the 1974 congress acknowledged the need to “consolidate the unity between the peoples of Africa and of African descent,” as had Du Bois. That congress’s “General Statement on Economics” declared that the purpose of economic development was “the liberation of our people at home and in the diaspora.” The “Resolution on Democratisation of International Institutions,” also from the 1974 congress, recommended that African regional and subregional organizations permit the participation of “counterpart organizations in the Caribbean and North America.”

CONTINUING ORGANIZATIONS
The international Pan-African meetings held between 1900 and 1945 established four organizations intended to be permanent. These were the Pan-African Association, 1900–1902; the International Pan-African Association, 1921–1925; the New York Pan-African Congress Committee, 1923–1927; and the Pan-African Federation, 1944–1947. The headquarters of these four organizations were located in the very capitals of the colonial countries the conferees wished to displace: London, Paris, and New York.

POST-MANCHESTER CONGRESSES
Between 1945 and 1974 most Pan-African activity took place on the African continent. The 1945 congress was organized by George Padmore and Kwame Nkrumah, the latter of whom was inspired by black nationalist Marcus Garvey. A native of Trinidad, Padmore was a former law student at Howard University who became an important official of the Communist International. Nkrumah, who graduated from Lincoln University and the University of Pennsylvania, became the first president of an independent Ghana in 1957, the foremost advocate of Pan-Africanism during this period, and the principal founder of the Organization of African Unity (OAU) in 1963. The Sixth Pan-African Congress resulted from the long-term actions, sometimes in concert, but often not, of three men: Julius K. Nyerere (1922–1999) of Africa, Adam Clayton Powell Jr. (1908–1972) of North America, and C. L. R. James (1901–1989) of the Caribbean. At the Cairo summit meeting of the Organization of African Unity (OAU) held in July 1964, which was attended by Malcolm X, Nyerere, then president of Tanzania, introduced and negotiated to passage a resolution recognizing the Afro-American struggle as a concern of the OAU.

In an October 17, 1967, address titled “After the Arusha Declaration,” Nyerere invited foreigners, including African Americans, to come to Tanzania to assist in nation building. In the late 1960s Nyerere went to Harlem and issued an invitation to African Americans to come to Tanzania to assist in building a socialist African state. As a result of these efforts, the number of African Americans in Tanzania increased rapidly to about eight hundred in 1974. Among the most important for the Sixth Pan-African Congress were Sam Dove and Bill Sutherland. Dove served as a consultant to the Tanzanian government on the sixth Pan-African congress. Sutherland was the founder of the Congress of Racial Equality (CORE), a founder of the American Committee on Africa (ACA), a consultant of President Nkrumah, and a liaison between
the Tanzanian government and the African American community in Tanzania. Also resident in Dar es Salaam at this time was Walter Anthony Rodney, a Guyanese.

The Black Power Conferences were initiated in Washington, D.C., in 1966 by Powell, a U.S. congressman who had participated in the 1945 Manchester congress. The Newark Black Power Conference of July 1967 resolved to sponsor “an International Black Congress.” Chairing the economics workshop was Robert S. Browne of Fairleigh Dickinson University. The Philadelphia Black Power Conference of the late summer of 1968 resolved to thank the government of Tanzania for its invitation to hold the Fourth Black Power Conference in Tanzania. This could not be arranged, however, and so at the Bermuda Black Power Conference of July 1969, C. L. R. James chaired a workshop on “Politics,” including a sub-workshop on “Pan-Africanism.” His closing address to the conference advocated a new Pan-African congress. James, a Trotskyite socialist, was a professor at the Federal City College and Howard University, both in Washington, D.C., from 1966 to the mid-1970s, and from this base he began preparing a new congress in 1970.

James formed an entirely new group consisting of the principal survivors of the Manchester congress, or their widows and ex-wives, and some of his students. Most important of the veterans were T. Ras Makonnen, Amy Ashwood Garvey (1897–1969), and Shirley Graham Du Bois (1907–1977), who lent their names as sponsors of the new congress. James’s students included Walter Rodney; Courtland Cox, formerly of the Student Nonviolent Coordinating Committee; and Marvin Holloway. The organizing group, based in Washington, D.C., styled itself the Provisional Secretariat for a Sixth Pan-African Congress.

The group organized itself into regional committees for North America, the Caribbean and South America, and Africa. European, Asian, and Pacific organizations and individuals were recognized by the secretariat on an ad-hoc basis. In 1972 the organizing committee issued a “call” to the Sixth Pan-African Congress, written largely by James, Rodney, and Cox. Two years later it issued a briefing paper. Rodney contributed a paper, “Toward the Sixth Pan-African Congress: Aspects of the International Class Struggle in Africa,” which was distributed by the organizers in April 1974. A 1945 Du Bois speech, “The Pan-African movement,” was reprinted and issued by the organizers, also in 1974.

Three regionwide meetings took place in North America—at Kent State University, at the Center for Black Education (CBE) in Washington, D.C., and in Atlanta. The Temporary Organizing Committee for a Sixth Pan-African Congress was established, with headquarters in Washington. Cox of the CBE was elected international secretary-general by acclamation. Sylvia Hill of the CBE was elected secretary-general for North America, and Julian Ellison of Columbia University and the Black Economic Research Center (BERC) was elected associate secretary-general for North America. This trio was denominated the Temporary Secretariat. James Turner of Cornell University accepted a Secretariat invitation to head the actual North American delegation, which had not yet been selected. At a regionwide meeting in Atlanta, Cox, Hill, and Ellison were formally elected as permanent officers. Cox then left for Dar es Salaam, taking with him several staff workers, including Geri Stark, who served as information officer.

In March 1974 the Caribbean and South American Regional Steering Committee elected Eusi Kwayana chairman, with Tim Hector and Maurice Bishop among those selected as delegates. However, no official nongovernmental delegation from this region was finally permitted.

The Sixth Pan-African Congress opened on June 20, 1974, in Nkrumah Hall at the University of Dar es Salaam. In the first order of business, Nyerere was elected president of the congress by acclamation. Conducting the opening plenary session as co-masters of ceremonies were Cox and Aboud Jumbe, the vice president of Tanzania. A taped message from Ahmed Sékou Touré, president of Guinea, was played. Papers were presented on the three major issues of the congress—politics, science and technology, and economics—the last of which Ellison persuaded the Secretariat to add. Two speeches, by Samora Machel and Peter Onu, deputy secretary-general of the OAU, were devoted to politics. The economics paper was by D. M. Nomvete of the United Nations Economic Commission for Africa. The congress proceeded with daily plenary sessions followed by simultaneous sessions of committees A, B, and C, for political; economic development; and African science, technology, education, and culture, respectively.

The Seventh Pan-African Congress convened in April 1994 in Kampala, Uganda. The organizers, led by Naiwu
Osahon of Lagos, Nigeria, included no one who had participated at the Dar es Salaam or earlier congresses.

THE AFRICAN UNION

In 2002 the OAU was replaced by a new organization, the African Union (AU), which was a more politically and economically integrated confederation of African states. By this time, all former colonies on the continent, as well as South Africa, were ruled by Arab or black governments, as were all colonies in the Caribbean except those of France. The AU represented the near accomplishment of the dream of Williams, Du Bois, Marcus Garvey, George Padmore, James, and Kwame Nkrumah.

PAN-AFRICANISM

Pan-Africanism is a political, ideological, and cultural movement centered on the liberation of Africa and Africans both on the continent and in the diaspora. The primary tension in the history of the movement has been the precise nature and relative importance of race and class, and their relation, in this struggle (Allen 1969).

There are many definitions of Pan-Africanism, and even debate about when it began and what actors and actions constitute the movement. These different conceptions hinge largely on whether one is referring to an organized historical movement self-identified as “Pan-Africanism” that began in the late nineteenth century and continues into the twenty-first. The alternative is a “general sentiment of international black kinship” (Weisbord 1973, p. 7n), sometimes written with a lowercase p (i.e., “pan-Africanism”; cf. Shepperson 1962), identified as existing as far back as ancient Egypt (Nantambu 1998), including slave revolts and (inter)nationalist tendencies in the Caribbean and Americas in the eighteenth and nineteenth centuries associated with such names as Nat Turner, Paul Cuffee, Denmark Vesey, Toussaint-L’ouverture, Joseph Cinque, Martin Delaney, David Walker, Edward Blyden, and many others. The remainder of this entry focuses primarily on the first, the contemporary organized movement, though their predecessors have always been explicitly recognized and honored.

The first Pan-African conference, held in London in 1900, was organized by Henry Sylvester Williams, a Trinidadian barrister, and attended by W. E. B. Du Bois. The group had previously formed under the title of “African Association” but changed it to “Pan-African Association” and committed to a conference every two years, the next to be held in the United States (Esedebe 1994, p. 44). The movement, a response to racism and colonialism, promoted civil and political rights for and cooperative development among all those of African descent—on the continent and in Europe, the Caribbean, and the rest of the Americas (Legum 1962).

Du Bois organized and led the second conference, often regarded as the “first” Pan-African Congress, in 1919.
followed by congresses in 1921, 1923, and 1927. The nineteen years between the first and second meeting were not without activity, however. Debates between those who did and did not support repatriation, between those who saw the issue primarily in racial terms and those who gave more weight to economic considerations, and between conservative accommodationists and liberal or radical liberationists were all lively, and included not only Du Bois but Marcus Garvey and Booker T. Washington. But the period from the end of World War I to the end of World War II marked an important and intensive growth of the organized movement, with its concerns reflecting developments worldwide. This activity included, but was not limited to, a number of important publications by leading Pan-Africanists, such as C. L. R. James (The Black Jacobins), Jomo Kenyatta (Facing Mount Kenya), and George Padmore (How Britain Rules Africa).

Many participants and observers alike have remarked on the changes that came with the first post–World War II Congress, the Fifth Pan-African Congress, held in Manchester, England, in 1945. As Kwame Nkrumah emphasized, for example:

For the first time, there was strong worker and student participation, and most of the over two hundred delegates who attended came from Africa. They represented re-awakening African political consciousness; and it was no surprise when the Congress adopted socialism as its political philosophy. Two declarations were addressed to the imperial powers, one written by Du Bois, and the other by myself. Both asserted the right and the determination of colonial peoples to be free, and condemned capitalism. (Nkrumah 1973, pp. 42–43)

At the same time, the interwar period had been one in which the Communist Party attacked Pan-Africanism as “petit bourgeois nationalism,” while official U.S. and European governments and the media portrayed the movement as completely under the control of Moscow and the Communists. The Fifth Congress, then, was seen as the end of the “coming-of-age” period of Pan-Africanism, whose leaders and proponents were now consciously “seeking a way of achieving national liberation and economic emancipation without allying themselves with the Communists” (Padmore 1971, p. 130). The formation and mobilization of colonial liberation movements in the postwar period led to Ghana’s independence in 1957, when “Pan-Africanism moved to Africa, its real home, and Pan-African Conferences were held for the first time on the soil of a liberated African state” (Nkrumah 1973, p. 43).

In the period of decolonization that began with Ghanaian independence, a growing continental Pan-Africanism in which continental political and economic unity was envisioned was strongly promoted by Nkrumah (1963), Cheikh Anta Diop ([1960] 1978), and others. One of the issues hotly debated in this period regarded the relation of North Africa to sub-Saharan Africa. Continental Pan-Africans viewed the North as African, while “sub-Saharan” Pan-Africanists, concerned with Pan-Negroism versus Pan-Arabism, did not include the North in their proposals. This debate also overlaps with and touches on many issues relevant to cultural Pan-Africanism, in which all Africans—continental and diasporan—are seen as sharing many cultural and even linguistic characteristics that distinguish them from other non-Africans, especially Europeans (Marah 1998, p. 80). Some of the divisions were represented on the continent by the rivalry between the Brazzaville and Casablanca groups, which resulted in a “compromise” with the creation of the Organization of African Unity (OAU) in 1963. In the diaspora, these divisions were reflected in the debates between cultural nationalists (some who eventually embraced Afrocentricity) and political (or revolutionary) nationalists, including those coming out of the civil rights and Black Power movements, such as Stokely Carmichael (Kwame Ture).

But the tradition of continental and diasporan alliance was continued as Malcolm X, founder of the Organization of Afro-American Unity (OAAU) attended the OAU’s Cairo Summit in 1964, where he spoke in favor of the inseparable connections between Africans “at home” and abroad that could not be ignored, and author Richard Wright attended the Bandung Conference in 1955. These developments were also played out in the rise of black studies courses and curricula in the 1960s, including the establishment of the Afro-Asian Institute at Temple University in Philadelphia in 1969, later reorganized and renamed the Department of Pan-African Studies (including its Pan-African Studies Community Education Program, or PASCEP) in 1972. Bandung, the Non-Aligned Movement, and the Afro-Asian Institute are examples of what Mazrui identified as the growing “Global Pan-Africanism” uniting not only continental and diasporan Africans but other colonized or previously colonized peoples of ASIA and the Americas (Mazrui 1977). Malcolm X’s experiences in Mecca and elsewhere and Martin Luther King Jr.’s position on Vietnam later in life, even the haiku and tanka poetic forms of Richard Wright and Sonia Sanchez, were all manifestations of global Pan-Africanism.

In the twenty-first century, the Pan-African notions of African political unity and continued discussion of the relation and relevance of racism and capitalism remain alive. With the fall of the apartheid government in South Africa, political independence has been achieved, but neocolonialism remains alive and gives no indication of with-
ering away on its own. In the diaspora, although there remains tremendous racial residential segregation and strong evidence of ongoing discrimination, those of African descent have obtained positions of authority and power in the political and economic spheres, resulting in what might be viewed as “domestic neocolonialism.” In the face of all these developments, Pan-Africanists such as Shivji are promoting “an alternative Pan-Africanism of the People, rooted in anti-imperialism and liberation. In other words, the nationalism of the twenty-first century is Pan-Africanism rooted in anti-imperialism” (Shivji 2006).

PAN-ARABISM

Pan-Arabism is a Western term for the ideological and political project Arabs refer to as Arab nationalism. This project’s central premise is that all those who speak Arabic, from Iraq in the east to Morocco in the west, share a common history, heritage, and culture, and are therefore members of a single nation whose destiny it is to overcome the artificial boundaries imposed by colonialism and achieve independence and unity.

Like all nationalisms, Arab nationalism claims ancient roots but is actually of relatively recent origin. The term Arab was used by neighboring peoples to designate an ethnos based in the central and northern Arabian Peninsula from well before the emergence of Islam in the seventh century CE, and among Muslims the Arabs enjoyed a distinctive status as the people to whom God chose to send his final and most complete revelation, transmitted by an Arab prophet, Muhammad (c. 570–632), in the Arabic language. But in the later Ottoman period, the term was often used by literate urban folk to denote the uncultured nomads of the desert. Premodern identities in what is today called the Middle East were generally framed in religious, kinship, tribal, occupational, and local or regional terms, or in terms of one’s loyalty or subjection to a particular ruler or state, such that before the nineteenth century no one in what is now referred to as the Arab world would have considered oneself an Arab in the modern national sense of the term.

Arab nationalism was a product of the social, cultural, and political transformations that the predominantly Arab provinces of the Ottoman Empire underwent in the second half of the nineteenth century and the first decades of the twentieth century. These transformations included the disruptive effects of the region’s growing integration into a Europe-centered world economic and political order; efforts by the Ottoman ruling elite to centralize power and create a modern state that could withstand European encroachment and counter separatist movements among its subject Christian peoples; the spread of modern schools; and the complex encounter with European ideas, institutions, and practices, disseminated and mediated largely through new print media. These processes helped
foster what would come to be called the *nahda*, the Arab cultural “renaissance” that was centered in Ottoman-ruled geographic Syria (encompassing the present-day states of Syria, Lebanon, Israel/Palestine, and Jordan) and in Egypt, which opened the way to a protonational and largely cultural “Arabism.”

After the Ottoman constitutional revolution of 1908, politically active Arabs (largely from the educated upper and middle classes) tended to advocate greater autonomy for the Ottoman Empire’s Arab provinces while remaining loyal to the Ottoman framework, seen as the only bulwark against European colonial domination; only a few marginal groups and individuals went so far as to call for Arab independence from Ottoman rule. But after the outbreak of World War I in 1914, Ottoman repression and centralization, as well as wartime hardships, alienated many Arabs from Ottoman rule. Meanwhile the British, seeking local allies against the Ottomans, established secret links with Husayn (c. 1854–1931), the quasi-autonomous ruler of the holy city of Mecca, who hoped to escape Ottoman control and carve out a state for himself and his Hashemite clan, and through him with Arab nationalist activists in Syria. In 1915, bolstered by Britain’s promise to support postwar Arab independence under Hashemite rule and equipped with British weapons, money, and advisors, the Hashemites and their allies revolted against Ottoman rule in the name of “the Arab nation” and participated in the Allied military campaign that eventually defeated the Ottoman forces.

It was only with the end of Ottoman rule over the Arab provinces that significant numbers of their inhabitants began to see themselves as Arabs in a new national sense, though that identity was never uniform, uncomplicated, or uncontested. Arab nationalist hopes for independence and unity were soon frustrated as the victorious Allies reneged on their wartime promises and instead divided the former Ottoman Arab provinces into several new states ruled by Britain or France as “mandates,” which their new subjects accurately perceived as a thinly disguised form of colonialism. Arab nationalists held fast to their vision of a unified Arab nation; yet over time distinctive national identities (Syrian, Lebanese, Iraqi, Palestinian, and so on) took root in these new states, often in tension with a widespread and persistent but contingent sense of common pan-Arab identity. This tension was further complicated by the fact that many of the new “Arab” states contained substantial minorities that were either non-Arab (e.g., the Kurds in Iraq) or non-Muslim (e.g., Christians in Lebanon), or came to be dominated by minority groups (e.g., the Alawites in Syria, the Sunnis in Iraq).

As the eastern Arab lands won independence from colonial rule in the 1930s and 1940s and many Egyptians began to see their country as part of a wider Arab world, the question of Arab unity came to take center stage. The League of Arab States, established in 1945, proved ineffective, and in the 1950s the cause of Arab unity was championed by a new pan-Arabist movement based in Syria and Iraq (the *Ba'th*, from an Arabic term for “renaissance”) and by the new regime in Egypt led by Gamal Abdel Nasser (1918–1970). Despite the rhetorical commitment of key Arab leaders to pan-Arab unity, however, the only real experiment in unification—the merger of Egypt and Syria into the United Arab Republic in 1958 under Nasser’s leadership—founded after just three years. Israel’s victory in the June 1967 Arab-Israeli War was a major defeat for the radical Arab nationalism espoused by both Nasser and his Ba’thist rivals. Thereafter, Pan-Arabism as a political project went into decline, sidelined by authoritarian regimes (whichever monarchical or republican) concerned mainly with their own survival and rejected by the Islamist movements that emerged as those regimes’ main opposition.

Nonetheless, thanks to transnational migration, the spread of literacy and mass communications, and more recently pan-Arab satellite television broadcasting, many Arabic speakers today participate in a common cultural-political field in which the same cultural products are consumed and what are perceived to be common problems are addressed, including autocracy, economic underdevelopment, social inequality, the plight of the Palestinians, and U.S. hegemony and intervention. As a result, despite the continuing salience of separate state nationalisms, distinctive local forms of spoken Arabic, the deep divisions within the Arab world, and its failure to achieve even a modicum of equitable economic integration, much less pan-Arab political unity, a variable and contingent but nonetheless significant sense of common Arab identity (and sometimes solidarity) persists.

PAN-CARIBBEANISM

The emergence of Pan-Caribbeanism—a movement dedicated to regional economic and political integration—can only be understood in the context of the Caribbean's history, from plantation system and slavery, to anti-colonialist struggles and eventual independence. The attempt to integrate the region economically and politically dates back to the eighteenth century, when British colonial authorities sought confederation of the Leeward Islands. Other attempts occurred in the late nineteenth century and early twentieth century, but met with no success. Indeed, no serious consideration of West Indian Federation was made until the mid-1940s.

Some scholars suggest that the idea of the West Indian Federation originated with colonial officials and that federation was thought of as a way of reducing the cost of governing the colonies. Other analysts believe that the plan was hatched by West Indians living in the region and abroad, and was intended as a transitional phase leading to independence. Whoever was behind the idea of the British West Indies Federation, it was conceived as an attempt to centralize the economy and political administration of the region. Prominent West Indians, including businessmen, union leaders, and local politicians, saw the plan as a viable solution to the challenging economic situation facing the region. It was not, however, until the Montego Bay conference of 1947 that serious consideration was given to federation. A combination of factors contributed to Britain's stronger interest in the plan. First, between the two World Wars, Great Britain had experienced a series of setbacks that had forced the reorganization of its empire and the loss of some of its colonies. Independence movements in Australia, Canada, New Zealand, the Union of South Africa, India, and other British colonies were exerting pressure on the home government. Second, the West Indian colonies had seen widespread disturbances and rebellions by workers during the 1930s, and labor union leaders were becoming increasingly militant. West Indian workers’ demands included better working conditions, better salaries, universal suffrage, self-government, and federation. British colonial officials saw these demands as necessitating changes in colonial policy.

West Indian leaders, however, were suspicious of British intentions. As a result, it took several meetings over a ten-year period for all concerned parties to even agree on an agenda. These meetings and dispatches from West Indian leaders and British colonial officials reveal the frustration and ambivalence of many of the proponents of federation. The Moyne Commission report of 1940 exposed the persistent economic neglect experienced by the British West Indies, but argued that the islands were not ready for economic federation. Indeed, federalism was never presented as a viable path to the economic and political development of the region; it was simply a way to cover up for failed colonial policy. It was also perceived by West Indians as a British attempt to sabotage the decolonization process.

In 1956 a conference was convened in London in which it was debated whether the federation would facilitate the eventual achievement of the islands’ self-government. Some argued that if Britain accepted the idea of a federation, it would surrender its imperial authority. Despite the debate, a federal constitution was drafted. It established that the unit members of the federation would be under the mandate of a governor-general appointed by the crown. The government would consist of a prime minister, a cabinet, a council of state, a house of representatives—in which the number of representatives from any given island would be based on that island’s population—and a senate. Trinidad was selected as the federal capital.

The West Indian Federation took effect in 1958. It included the islands of Antigua and Barbuda, Barbados, Dominica, Grenada, Jamaica, Montserrat, Saint Kitts-Nevis-Anguilla, Saint Lucia, Saint Vincent, and Trinidad and Tobago.

From its conception to its implementation, the West Indian Federation was destined to fail. Some analysts observe that the federation of fifteen scattered islands, separated by hundreds of miles, was an inherently difficult process. These islands’ leaders also had to overcome insular attitudes and regionalism. More importantly, the real test of the federation was whether the larger islands were prepared to help the smaller islands escape their desperate economic plight. Unfortunately, the weak economy of the smaller islands became a burden for Jamaica and Trinidad. Some have suggested that federation failed because narrow nationalism prevailed over Pan-Caribbeanism. The call for federation emerged at a time when some of the islands were caught up in intense nationalist fervor. For example, achieving national independence dominated the agenda of Jamaica’s People’s National Party (PNP), despite party leader Norman Manley’s support for federation. As a result, neither the PNP nor the Jamaican people embraced federalism. Nationalism also exacerbated tensions between Trinidad and Jamaica. The Jamaicans expressed their discontent with the federal constitution and with representation in the federal parliament. Jamaica, with a population of 1.5 million, held seventeen seats—whereas Trinidad, with 750,000 inhabitants, held seven seats, and Barbados, with 230,000 inhabitants, had five seats. Nationalist fervor in Jamaica pushed the Jamaica Labour Party, led by Alexander Bustamante, to call for a referendum, and in 1961 Jamaicans decided to leave the federation. Inevitably, with Jamaica's withdrawal from the
federation, Trinidad decided there was no reason for it to remain either at a time when its economy was taking off.

The withdrawal of the largest islands from the federation stalled progress for the rest of the islands. Economic integration was achieved by the creation of a less ambitious organization called the Caribbean Free Trade Area (CARIFTA), which later was transformed into the Caribbean Community (CARICOM). In 1962 the West Indian Federation was dissolved. After its dissolution, there was some discussion of creating an Eastern Caribbean Federation, with Trinidad as the leading country. Arthur Lewis, then the vice-chancellor of the University of West Indies, led discussions with Trinidian Premier Eric Williams, British colonial officials, and the rest of the leaders of the islands involved about forming this new federation. However, when the scheme was welcomed in London, Williams decided to take Trinidad out of the proposed federation.

The West Indian Federation lasted for less than four years, but despite its brief existence it strengthened West Indians’ yearning for political independence. The dissolved federation triggered a movement toward independence in the British West Indies, including the separation of the University of the West Indies from the University of London. Regardless of whether the West Indian Federation was an attempt to paper over the shortcomings of British colonial policy or a failed attempt to create regional cooperation, it helped lead to the decolonization of the Caribbean.

PANEL STUDIES

A panel study is a type of nonexperimental longitudinal study design that samples (using random or stratified random methods) a population to identify a set of respondents, then recontacts the same respondents repeatedly over time. A traditional panel study differs from a trend study in that a trend study samples the same population repeatedly but with different respondents at each time point. A panel study is similar to a traditional epidemiologic cohort study in that a sample or cohort is followed over time. However, the purpose of following participants in a traditional cohort study is to allow enough time to be able to observe a particular outcome and determine how exposure to a certain variable is associated with the outcome. In contrast, the purpose of following participants in a panel study is typically to observe changes on a particular variable over time to potentially relate those changes to an outcome of interest or explain what factors may lead to the changes in the variable over time. Thus, a panel study often includes multiple measurements of variables, usually at regular intervals, over a circumscribed period of time.

Compared to other nonexperimental study designs such as case-control or cross-sectional studies, a carefully conducted panel study can strengthen the case for inferring causation because temporality (i.e., the cause precedes the effect in time) is more accurately preserved. In panel studies, a researcher is also able to determine the strength of an association between an explanatory variable and an outcome. However, specificity or the degree to which a cause leads to a single effect is not as high as it is
in a randomized controlled trial or experimental study. Thus, in panel studies statistical controls for group non-equivalence are often employed. A further advantage of panel studies is that they allow for complex statistical modeling of dynamic phenomena (e.g., latent growth modeling and other types of trajectory analyses) that may more accurately reflect reality.

One primary disadvantage of panel studies is the problem of selective attrition over time. Participants who remain in the panel over time may be qualitatively different from the participants who are lost to follow-up due to relocation, lack of interest, or death. Another disadvantage is that panel studies can be quite costly as they require measurements at multiple time points, and tracking highly mobile respondents can be a challenge. Panel studies are strengthened when the measurement protocol or instrument remains the same over time. However, this can be difficult to maintain because of emerging technological advances in instruments or measurements or the difficulty in measuring the same phenomena during developmentally different phases of life. A change in the measurement protocol or instrumentation makes it difficult to determine if an observed change in the data is the result of measurement protocol changes or of actual changes. Finally, panel surveys can also be fatiguing to participants, leading to selective attrition, or participants may become primed to the instrument or measurement protocol, leading to atypical responses. Large scale, well-conducted panel studies include the Panel Study of Income Dynamics, National Longitudinal Surveys, the Health and Retirement Survey, the National Longitudinal Study of Adolescent Health, Coronary Artery Risk Development in Young Adults, and the Framingham Heart Study.

PANEL STUDY OF INCOME DYNAMICS

The Panel Study of Income Dynamics (PSID) is a longitudinal study of a representative sample of U.S. individuals and the families in which they reside. The PSID emphasizes the dynamic aspects of family economics, demography, and health. Data have been collected since 1968, making the PSID the longest running panel on family and individual dynamics. It has consistently achieved response rates of 95 to 98 percent, and as of 2005, 8,041 families were currently participating in the survey. Over the years, the PSID has collected information on nearly 70,000 individuals spanning as much as thirty-seven years of their lives.

Through multiple waves collected over long time periods, these data are the only data ever collected on life course and multigenerational health, well-being, and economic conditions in a long-term panel representative of the full U.S. population. The PSID has collected data on employment, income, housing, food expenditures, transfer income, and marital and fertility behavior annually between 1968 and 1997, and biennially between 1999 and 2005. Additionally PSID collects data on health status, health behaviors, health care utilization, health insurance, and philanthropy. Beginning in 1985 comprehensive retrospective fertility and marriage histories of individuals in the households have been assembled.

The PSID sample, originating in 1968, consists of two independent samples of the U.S. population: a cross-sectional national sample and a national sample of low-income families. The Survey Research Center (SRC) drew the cross-sectional sample (known as the “SRC sample”), which was an equal probability sample of households from the forty-eight contiguous states designated to yield about 3,000 completed interviews. The second sample came from the Survey of Economic Opportunity (SEO) conducted by the Bureau of the Census for the Office of Economic Opportunity. In the mid-1960s, the PSID selected about 2,000 low-income families with heads under the age of sixty from SEO respondents. The PSID core sample combines the SRC and SEO samples.

PANEL STUDY OF INCOME DYNAMICS
Panic

From 1968 to 1997 the PSID interviewed individuals from families in the core sample every year, whether or not they were living in the same dwelling or with the same people. Adults have been followed as they have grown older, and children have been interviewed as they advance through childhood and into adulthood, forming families of their own. In 1997 the PSID changed from every-year interviewing to every-other-year interviewing. Moreover, a sample of 441 immigrant families was added to enhance the representativeness of the sample.

In 1997 and again in 2002, the PSID supplemented its main data collection with information on PSID parents and their children in order to study the dynamic process of early life experiences. The supplement, called the Child Development Supplement (CDS), included a broad array of development measures, including: (a) age graded assessments of cognitive, behavioral, and health status of children obtained from the caregivers and the child/youth; (b) a comprehensive accounting of parental/caregiver time inputs to children as well as other aspects of the ways in which children and adolescents spend their time; (c) teacher-reported time use in elementary school; and (d) other-than-time use measures of additional resources, for example, the learning environment in the home, teacher reports of school resources, and decennial-census-based measurement of neighborhood resources. In 1997 CDS-I collected data on 3,563 children aged zero to twelve in 2,394 families. Five years later, CDS-II re-interviewed 2,021 of the CDS-I families, providing data on 2,907 CDS children and youth.

In calendar year 2005 alone over 5,500 unique users (i.e., unique IP addresses) downloaded more than 32,000 data sets from the PSID Data Center. The PSID Web site received over 1.6 million hits in 2005. Since its inception, over 2,000 journal articles, books, book chapters, and dissertations have been based on the PSID, and today a paper is published in a peer-reviewed outlet roughly every four days. The study was named one of the National Science Foundation’s (NSF) “Nifty Fifty,” the most notable NSF-funded inventions and discoveries in NSF history, 1950–2000.

It is difficult to briefly summarize the scientific impact of the PSID. Additional detail is provided on the PSID Web site. Areas of significant contribution include intergenerational transmission of economic status, children’s time use, the dynamics of poverty and economic status, resource sharing among extended family members, the interconnection between well-being and marriage and fertility, and neighborhood effects on individual social and economic outcomes.

PANIC

The term *panic* is used with a vast variety of meanings by the population at large, as well as by professionals and research scientists in different disciplines. For example, economists talk of financial or stock market panics, scholars of popular culture discuss moral panics or widespread public anxieties about deviant behaviors, and journalists sometime refer to certain kinds of hoarding or buying activities as an expression of panicky behavior. However, this entry confines itself to the two major usages of the term in the scientific and professional literature, which have little to do with the examples just given.

Even the two major usages differ. Along one line, there is an identification of panic with certain kinds of overt behavior by a number of people, such as rapid physical flight from a situation perceived as highly and personally dangerous to individuals in the collectivity involved. Sociologists have primarily used the term this way, and to a lesser extent so have psychologists. The other use of the term has reference to a mental state characterized by a sudden and extreme anxiety attack, with the person being unable to perceive any obvious reason for the reaction. Psychiatrists and other mental health professionals, who have been the primary students of this phenomenon, call it panic disorder.
Apart from using the same term, panic, there is otherwise very little in common between the two approaches. Interest in and study of the phenomena have had radically different origins and have involved different kinds of research by different specialties. In addition, the end goal of the research has differed. Those looking at panic disorder have increasingly come to believe that the mental problem can be dealt with through therapeutic and other measures. Those interested in flight behavior initially thought that understanding such behavior would be useful for disaster planning and crisis management purposes. However, as more empirical studies of disasters have been undertaken, many researchers have increasingly argued that the very concept of panic should be abandoned as a useful concept for scientific research. They argue that what occurs can be much better understood through other concepts, such as social roles and social relationships.

PANIC AS A SUBTYPE OF ANXIETY DISORDER
Panic disorder involves unexpected and repeated episodes of intense anxiety attacks accompanied by physical symptoms that may include chest pain, shortness of breath, heart palpitations, abdominal distress, trembling, dizziness, and a sense of unreality. An attack generally peaks within ten minutes, although some symptoms may last much longer. Many of those suffering from the disorder develop intense anxiety between episodes because they worry when and where the next one will strike. Routines of everyday life can be totally disrupted.

According to the U.S. National Institute of Mental Health, in any given year 1.7 percent of the American population will have a panic disorder. Females are twice as likely as males to develop panic disorders. Panic disorder usually occurs in early adulthood. Roughly half of all people who have panic disorder develop the condition before the age of twenty-four. Such statistics ought to be treated with caution, however; panic attacks are sometimes misdiagnosed and missed because many of the symptoms resemble heart attacks. Also, not everyone who experiences a panic attack will develop panic disorder; people can experience one attack but never have another.

What exactly causes the disorder is unknown. Heredity is probably involved, since the disorder seems to run in families. But there is also evidence that very stressful life events are a factor.

Fortunately, two types of treatment are available for panic disorder. There are medications that can keep symptoms under control as long as the prescribed medication is used. There are also specific kinds of psychotherapy that can teach sufferers how to view panic attacks differently, as well as ways to deal with the anxiety between attacks. Reports on success rates vary considerably, but it appears that a majority of those treated are helped. However, since panic disorder often coexists with other disorders and physical ailments, restoration to a less stressful life is also dependent on treatment of these other problems. Information on panic disorder and its treatment is available on the Internet, but care should be taken to ensure that such reports are from legitimate medical sources.

PANIC FLIGHT AS A FORM OF COLLECTIVE BEHAVIOR
In the 1920s, sociologists interested in the study of collective behavior (which looks at nontraditional or emergent behavior) began discussing instances of panic in certain risky situations, such as a fire in a crowded theater. The prevailing idea was that panic involved extreme and groundless fear that spread in a contagion-like way, resulting in irrational flight behavior, with individuals trampling one another. This view of panic is still commonly depicted in disaster movies and television shows.

However, the emergence of systematic disaster studies in the mid-twentieth century led to some reformulations about the nature of panic and the conditions necessary for its emergence. Research has shown that panic flight, while not unknown, is extremely rare in disasters and similar kinds of crises. The notion that panic behavior spreads through contagion has been widely discredited. The behavior is not irrational from the viewpoint of those involved. There is no evidence that certain kinds of people are more likely to flee in panic. At worst, panic is antisocial rather than antisocial in that people do not regress to an animal-like response.

Panic flight also occurs only under specific conditions. Potential participants must believe that there is an immediate and certain risk to their own life. Contrary to stereotypic views, flight will not be attempted if there is a belief that one is completely trapped. In other words, there must be hope that escape is possible. Persons who break in panic know what they are afraid of, and they are moving away from a specific location (in contrast to a stampede, which involves convergence). It is fear, not anxiety, that prevails. Finally, what others are doing around a person is crucial. This social interaction can work both ways, but usually reinforces a tendency not to flee.

PANICS

Panics are social-psychological reactions to fear. Financial panics occur when investors react to the fear of capital losses by dumping assets, thus causing the collapse of a financial institution or financial market. Moral panics, as Stanley Cohen (1972) coined the term, are situations in which the public expresses not fear but righteous indignation in opposition to a deviant activity of a subgroup, perceived to threaten society and its values. As either social-psychological reactions or financial events, panics are commonly thought to evoke irrational escape-mob behavior—such as stampeding to escape a threatening situation—when rationally one would have less chance of injury with an orderly exit.

Exits in financial panics involve the mass conversion of real or less-liquid financial assets into liquid (or more-liquid) assets, typically money instruments. A sudden high volume of selling—as investors scramble to escape further anticipated capital losses—can abruptly depress or cause a “crash” in the price of illiquid assets. Financial panics known as bank runs entail the mass withdrawal of bank deposits precipitated by a fear that the bank may be unable to meet such a demand in the future. The bank run may be either a lobby run—with retail depositors lining up to convert bank deposits into cash—or it may be an attempt by wholesale and other institutional depositors to transfer funds out electronically. Such fears of illiquidity can, by forcing a distress sale of assets to meet liquidity demands, cause illiquidity and insolvency. As in all financial panics, a fear that the event will happen motivates action that increases the likelihood of the feared event occurring.

A run on a bank that forces insolvency and the suspension of credit facilities, or a market crash that impedes the operation of a significant financial market, heightens the risk of an economic crisis. The breakdown of a market or the sudden withdrawal of credit can adversely affect, on a large scale, the day-to-day commercial operations of organizations in the nonfinancial sectors of the economy. As Milton Friedman and Anna Schwartz (1963) suggest in their explanation of the Great Depression of the 1930s, financial panics can precede, both temporally and causally, economic crises in employment, production, and trade—crises that may extend well beyond the boundary of the original panic. The possibility exists, however, that causality runs instead from economic activity out to money and credit, as Peter Temin (1976) suggests. The historical evidence is sufficiently ambiguous to leave scope for much debate.

Theories of panics as the manifestation of a “crowd mind” turn on whether the observed collective behavior is contagious, convergent, or emergent. Theories of financial panics parallel loosely these psychosocial theories of panics, though such links most often appear only in motivational narratives.

The idea of a distinct crowd mind was introduced in 1895 by Gustave Le Bon with his psychological law of mental unity. Le Bon posited a view of the crowd as distinctly different from the individuals composing it. Through contagion—the spread of behavior from one participant to another—a distinct and distinctly irrational collective mind is formed. Special characteristics of crowds include “impulsiveness, irritability, incapacity to reason, the absence of judgment and of the critical spirit, the exaggeration of the sentiments, and others besides” (Le Bon 1896, bk. 1, chap. 2, p.17). In contagion theories of panics, the “individual” is lost, transformed into a member of a “herd,” acting irrationally in the commonsense meaning of the term articulated above.

Douglas Diamond and Philip Dybvig (1983), in the tradition of Friedman and Schwartz, model bank runs as an equilibrium outcome of random withdrawal and contagious panic. In their model, a sufficiently large withdrawal of bank deposits can threaten bank liquidity, spark a fear of insolvency, and thus trigger a bank run that in the absence of deposit insurance or some other means to ensure reimbursement will yield the feared outcome.

Rejecting Le Bon, Floyd Allport (1924) posited that the crowd mind was simply the aggregated, possibly intensified, feelings of individual participants subjected to the same external stimulant. Like-minded people converge to a crowd rationally in the sense that the crowd mind is wholly consistent with independent individual preferences. Unlike contagion theories, no transformation takes place, and observed similarities across crowd participants cause the collective, not vice versa.

Some authors have attempted to explain financial panics as the result of rational convergent behavior on the part of individuals who fear bank-system insolvency because of some external financial shock. Charles Calomiris and Joseph Mason (1997), for example, suggest that when depositors can observe a financial shock that threatens bank portfolios but cannot identify which banks are at risk, they run collectively on all banks. This asym-
metric information theory of bank runs as financial panics is, like Allport's symbolic convergent theory of crowd minds, “rational” in the sense that the collective run on banks is nothing more than prior shared motivations resulting in the clustering of like-minded depositors acting similarly.

As a third explanation of the crowd mind, the emergent norm theory of Ralph Turner and Lewis Killian (1987) permits convergence insofar as similarities draw people together. But Turner and Killian suggest that there is then the emergence of distinct collective features when unusual situations challenge traditional norms and social interactions shape crowd behavior.

Brenda Spotton Visano (2006) explicitly links the emergent norm theory of crowd mind to a socioeconomic explanation of financial panics. In a framework that adopts a credit theory of the business cycle similar to that which grounds Charles Kindleberger’s (1989) historical study of manias and panics, the panic emerges in a demoralized environment created by the combination of prevailing financial distress and a sudden actual loss of liquidity.

All agree that financial panics involve a substantial and typically abrupt change in asset liquidity. All agree as well that the beliefs of depositors motivate behavior that is self-fulfilling. The debate is over which theory best explains a given financial panic, with history again sufficiently ambiguous, leaving the question wide open for debate.

PARADIGM

A paradigm is a template, model, or framework. Paradigms can be used to create new objects, just as templates can be used as patterns when outlining or designing something new. In fact, the word paradigm has its roots in the Greek term for a side-by-side comparison. Within the philosophy of science, a paradigm is a general but distinct worldview or theory. The history of science is characterized by paradigm shifts.

The seminal work on paradigm shifts is that of Thomas Kuhn (1922–1996). His 1962 monograph, The Structure of Scientific Revolutions, described what is essentially a form of nonlinear progress within the sciences. Put simply, during phases of what Kuhn called “normal science,” individuals working in a scientific field share assumptions, perspectives, and methods, and knowledge accumulates in a linear fashion. There is progress, but all of the knowledge and information is constrained by the same set of premises and assumptions. It is in this sense that it is conceptually linear. Eventually the assumptions are brought into question and the inadequacies and limitations of the theories being used are recognized. At that point one or more assumptions may be questioned, and new empirical results may be difficult or impossible to explain. It is not just one theory or method that is inadequate; instead, the fundamental assumptions of a field are brought into question. A bit later an alternative perspective or paradigm is introduced that is so dramatically different from what came before it that the shift is clearly not just an extension of what came before, but a fundamental and overarching change within the field. Examples of major paradigm shifts underscore the magnitude of these paradigm shifts: Einstein’s theory of relativity is enormously different from the Newtonian physics that preceded it; Copernicus initiated a revolution of a similar magnitude; Darwin changed the way biologists thought about the Homo sapiens, and stimulated modern reconsideration of humanity’s role within nature.
In his review of paradigm shifts in the 1999 *Encyclopedia of Creativity*, Thomas Nickles suggested that research produced within a paradigm is highly convergent, whereas that produced when a shift between paradigms is occurring is highly divergent. Convergent thinking is not original nor creative. It involves finding conventional or correct answers and solutions to fairly well-defined questions and problems. Divergent thinking, in contrast, is often original and creative. It involves exploring new options; the thinking moves in different and often original and unconventional directions. Various theories of divergent thinking are also described in the *Encyclopedia of Creativity* (Runco 1999).

Kuhn (1963) also referred to the convergent and divergent thinking involved in normal science and in paradigm shifts. He felt there was "an essential tension" between them, and one that stimulated creative thinking as well as paradigm shifts. Kuhn wrote: "Something like convergent thinking is just as essential to scientific advance as is divergent. Since those two modes of thought are inevitably in conflict, it will follow that the ability to support tension that can occasionally become almost unbearable is one of the prime requisites for the very best sort of scientific research" (1963, p. 342).

Paradigm shifts introduce new rules and new problem-solving techniques. In fact, they often introduce new problems as well as solutions. This may sound odd, but such problem discovery is distinct from problem solving, and is an important part of the creative process. Psychologists studying creativity even include problem-finding skills as part of the creativity complex. There is more to paradigm shifts: They also introduce new taxonomies, new classifications of the phenomena under study, and new ideas. Significantly, much of the new thinking that characterizes new paradigms is preconscious. Indeed, many of the differences between paradigms (e.g., Newton's and Einstein's) reflect assumptions, which of course are by definition not consciously processed.

Nickles used two tree metaphors to describe the reclassifications that occur during normal science and those that occur during paradigm shifts. The former can be viewed as branching, where new findings and ideas suggest additional specific branches to the tree of knowledge (or perhaps remove an old branch). The research on creative thinking can itself be used as an example. At one point, creative thinking was equated with problem solving. That was the tree, so to speak, and new theories merely identified new kinds of problem solving. Then behavioral scientists realized that thinking is often the most creative when the individual actually identifies a new problem, rather than merely solves an existing problem. Nickles referred to this kind of breakthrough as "tree switching" because an entirely new tree—not just a new branch—is introduced. In dramatic paradigm shifts such as Einstein's, the old tree is completely dismissed. Nickles gave Mendeleev's theory of the periodic table of elements and Darwin's theory of evolution as examples of tree switching and true paradigm shifts.

Kuhn himself described normal science as progressing by working with exemplars. The basic idea here is that problem solving during a period of normal science depends on identifying similarities among problems and questions; and once the similarity is identified, a solution (which is itself analogous to previous solutions) is suggested. Kuhn even applied this to science education, where instruction and the curriculum rely on exemplars, analogies, and similarities. Paradigm shifts, in contrast, involve what Kuhn called "new disciplinary matrices." This was Kuhn's way of describing tree switching and entirely new perspectives within the sciences.

Note that disciplinary matrices are, for Kuhn, within the sciences. Indeed, Kuhn's theory of paradigm shifts initially focused on the hard sciences. The example above, concerning problem-solving and -finding extends this to the social and behavioral sciences. But the concept of paradigm shifts is now used much more broadly, even outside the sciences. The idea of paradigm shifts and the suggestion of questioning assumptions and nonlinear progress has proven to be very useful in organizational theory and management, for instance, and a large number of articles and programs outlined in business periodicals tie paradigm shifts to innovation. According to Nickles (1999), political debates and advertisements also regularly refer to paradigm shifts. Whether or not these meet the criteria presented by Kuhn is dubious, but the assumption that dramatic shifts of some sort are useful for creativity and innovation is obviously quite useful.

Criticisms of the theory of paradigm shifts underscore the retrospective and even post hoc method used by Kuhn, as well as the implication that normal science relies so heavily on analogies and "acquired similarity relations" (exemplars). Critics often note that normal science is much more inventive and creative than the original theory of paradigm shifts allowed. Alternative conceptions of scientific progress include the evolutionary perspective whereby changes do occur but they are more linear, perhaps the result of a natural selection process. If this is accurate, progress—even highly creative advance—is more gradual and less sudden than described by paradigm shifts. Of course, the interesting thing here is that the evolutionary perspective is itself an analogy, taken from the biological sciences. Still, it is no doubt useful to recognize that paradigm shifts themselves represent one theoretical framework and one set of assumptions. The theory is enormously useful, but not the final word on progress.
it was the final word, the theory of paradigm shifts would, in a manner of speaking, refute itself.

PARADOX OF VOTING

The most common form of the paradox of voting refers to a situation where the outcome of majority-rule voting over a discrete set of candidates produces no clear winner, even though each individual voter has a clear and transitive rank ordering of preferences over the alternative options. The paradox is that although individual preferences are transitive, the preferences of the majority are cyclical. Thus, although each individual voter has a most preferred candidate, a “reasonable” majority-rule method of voting produces no clear winner.

To see the paradox at work, consider this example. Adam, Bala, and Chen are three candidates for a position on the school committee. There are three voters, whose preferences are as follows:

First Voter: 1. Adam, 2. Bala, 3. Chen;

Who should be declared the winner if each voter declares their rankings? Two out of three voters (First Voter and Second Voter) prefer Adam over Bala. Similarly, two out of three voters (Second Voter and Third Voter) prefer Chen over Adam. Should Chen be declared the winner? Not quite. Two out of three voters (First Voter and Third Voter) prefer Bala over Chen, thereby leading to no clear resolution.

The potential for such a paradox was first noted by the marquis de Condorcet (1743–1794), the French mathematician, philosopher, and social scientist, in his Essai sur l’application de l’analyse à la probabilité des décisions rendues à la pluralité des voix (Essay on the Application of Analysis to the Probability of Majority Decisions, 1785). The voting method used in the example is the so-called Condorcet method, which can be summarized as follows: First, rank each candidate in order of preference (tied ranking is allowed), and then compare each candidate with every other candidate and find a winner for each pair-wise comparison. The candidate that tallies the biggest wins across all pair-wise comparisons wins the election; however, as suggested by the term paradox, there is no guarantee of a winner.

Since Condorcet, other scholars have discussed the paradox and its broader implications, most notably Kenneth Arrow in his seminal work Social Choice and Individual Values (1951). Arrow postulated five “rational” and “ethical” criteria that any social-welfare function must meet, and showed that there is no method of aggregating individual preferences over three or more alternatives that satisfies these criteria and always produces a fair and logical result. Much of the work on social choice theory that has followed Arrow’s results either validates his conclusions or attempts to find a way around them.

Subsequent authors have attempted to resolve the original paradox of voting in various ways, including one that involves using the Condorcet method first, and if it produces no resolution, then using an alternative such as the “Borda count.” In a Borda count, each voter assigns points to candidates in order of his or her preference: If there are $n$ candidates, each voter gives $n$ points to his or her top ranked candidate(s), $n - 1$ points to the second ranked candidate(s), and so on. There are different formulae for assigning points to each voter’s preferences, with higher points being assigned to higher ranked candidates. The candidate with the highest number of points aggregated across all voters wins.

Other approaches involve taking a multistage approach to finding a winner. In the first stage, if there is no clear winner, a second voting method is used whereby the candidates are restricted in some way, for example with the smallest set such that every candidate in the set beats all candidates not included in this restricted set (the “Smith set”). Other approaches involve the farsightedness of voters. Ariel Rubinstein (1980) introduced the “stability set,” which produces a winner when voters not only make pair-wise comparisons, but also think one step ahead. Yet, Bhaskar Chakravorti (1999) has shown that this notion is itself limited, and if voters do not ignore farsightedness on the part of other voters and are “consistently” farsighted (that is, they can consider comparisons...
Paranoia

Many alternative voting systems have been proposed to ensure a fair resolution in most practical situations. Common alternatives include run-off elections; approval voting, where voters cast a vote for all the candidates of whom they approve; and the Borda count.

A second version of the paradox of voting is attributed to Anthony Downs (1957). According to Downs's construct, a rational voter will refrain from voting because the costs of voting usually exceed the expected benefits. The probability of casting an election's decisive vote is too small to make the benefits worthwhile, whereas the cost of going out to vote and foregoing other activities is positive and quite tangible. The fact that voters do, indeed, participate in elections to vote is paradoxical, given such a rational calculation. Various theories have been put forward to resolve or explain the Downs paradox. Some have suggested that voters consider factors other than the private cost-benefit analysis to decide whether or not to vote. Some vote because they consider it a responsibility and a social duty, whereas others vote to gain satisfaction from the fact they have registered their preferences in some way, even if it is not decisive, and derive utility from participating in a democratic process.

PARANOIA

Paranoia is a term commonly used to describe people who are preoccupied with the idea that others are “out to get them” or “talking about them.” This common usage of the term by the lay public reflects a key feature of the concept in the social and behavioral sciences, particularly in the mental health literature. Constant worry about harm to the self is self-referential thinking. Self-referential thinking is a major feature of the paranoid condition. A paranoid person is also mistrustful, suspicious, and has an exaggerated sense of self-importance. These are the basic elements of paranoid thinking. The various ways that paranoia is discussed in the social and behavioral science literature include psychiatric classification, causal theories, and symptom-level approaches.

PSYCHIATRIC CLASSIFICATION

The fourth edition of the Diagnostic and Statistical Manual of Mental Disorders, or DSM-IV (American Psychiatric Association 1994), defines paranoia as a symptom of mental illness. The DSM-IV includes three types of mental illnesses or syndromes of which paranoia is a significant symptom: paranoid personality disorder, delusional disorder, and paranoid schizophrenia. Paranoid personality disorder involves strong feelings of suspiciousness, jealousy (in romantic relationships), and defensiveness without justification or evidence, but the individual does not have a psychotic illness such as schizophrenia. Delusional disorder is more severe and involves psychotic thinking, but the themes of the delusions are not bizarre. Instead, the themes of the paranoid delusions involve situations that can occur in real life such as a spouse cheating, being poisoned, or contracting an infectious disease. Finally, paranoid schizophrenia is the most severe form of mental illness in this category. The delusions are more bizarre, such as the belief that other people can read the patient’s thoughts or take them out of his or her head.

Attempts have been made to conceptualize paranoid personality disorder, delusional disorder, and paranoid schizophrenia as reflecting a continuum from mild to severe psychopathology, respectively. This perspective assumes that the type of delusional symptom defines the relationship between the different types of psychiatric disorders. Genetic studies of patients with delusional disorder using the family history method are one line of research that does not support the continuum perspective (Kendler, Masterson, and Davis 1985; Schanda et al. 1983). Schanda et al. (1983) found that risk for “atypical psychosis” was higher in the first-degree relatives of delusional disorder patients than in those of patients with paranoid schizophrenia. Kendler et al. (1985) found that paranoid personality disorder may have a stronger familial link to delusional disorder than to schizophrenia. These two findings are at odds with the notion that there is greater genetic vulnerability among patients with schizophrenia. Thus it may be more useful to consider paranoid symptoms apart from diagnoses.

CAUSAL THEORIES

Causal theories of paranoia fall into three basic categories: biological, psychological, and social. Biologically, Strider et al. (1985) claim that various neuropsychological impairments such as memory problems and hearing loss
Paranoia

associated with brain injuries or the cognitive decline that accompanies old age may engender paranoia because individuals may attribute their inability to find misplaced objects and inaudible conversations to the deliberate attempts of others to keep things from them. Moreover, both clinical and experimental data indicate that injury to the right hemisphere of the brain is more likely to produce paranoid thinking because of the inability verbally to label sensory and emotional experiences (Strider et al. 1985). Thus paranoid thinking may be manifested as a result of damage to the brain.

There may also be a genetic component to paranoia. Genetic studies of patients with delusional disorder using the family history method indicate that the percentage of first-degree relatives (i.e., parents, siblings, or offspring) with schizophrenia ranges from 0 percent to 3 percent and affective disorder ranges from 3 percent to 6 percent (Kendler, Masterson, and Davis 1985; Schanda et al. 1983). Bentall et al. (2001) argued that because diagnoses include multiple symptoms that involve multiple genes, heritability estimates may be higher for diagnoses than for paranoid symptoms alone. Taken together, these findings suggest that paranoid conditions have very limited inheritability, which may manifest differently in various forms of psychopathology.

Classical and modern psychological theories view paranoia as a defense against threats to the self. The classical theory of Freud defines paranoia as an unconscious defense against repressed homosexuality, chronic problems of self-esteem regulation, and sensitivity to narcissistic injury (Bone and Oldham 1994). The idea that paranoia protects against threats to self-esteem is the only aspect of Freudian theory that survives in modern theories of paranoia. Bentall et al. (2001) propose an attribution–self-representation model of persecutory delusions (i.e., paranoia). In their model, individuals make attributions for positive or negative events based on available self-representations stored in memory, which, in turn, influence future attributions in an ongoing cycle. Paranoia occurs when the individual attempts to engage in self-esteem regulation after experiencing a negative event, where the cognitive search does not yield a negative self-representation to explain the event, resulting in a shift to external-personal causes (Bentall et al. 2001). In other words, the person maintains a positive view of the self because those self-representations could not account for the negative event.

Social theories of paranoia emphasize that it is a reaction to threatening environments or inadequate resources (Mirowsky 1985; Marcus 1994). Marcus (1994) extends the psychoanalytic perspective to paranoid tendencies expressed by social groups in organizational contexts. He considers the paranoid reaction in social groups and organizations a manifestation of a survival instinct when there are behavioral constraints on members because of unequally distributed resources that are hidden or protected (Marcus 1994). Mirowsky (1985) proposes a similar theoretical explanation for paranoia in social groups. It is a form of self-protection from exploitation and oppression among social groups that are powerless. He demonstrated that paranoid beliefs in the general population are the product of interactions between feelings of mistrust and exposure to social environments that are threatening (Mirowsky 1985). This may be why paranoia appears to be more common among individuals in the lower social classes and among ethnic/minority groups (Mirowsky 1985; Whaley 1998). Self-protection is a theme that links biological, psychological, and social theories of paranoia. In this way, paranoia may be a coping response that is adaptive. However, extreme paranoia as evidenced in paranoid schizophrenia with no basis in social reality is dysfunctional.

SYMPTOM-LEVEL APPROACHES

Paranoia is not an all-or-none condition. It is best to think of paranoid symptoms as falling on a continuum of severity, with the mild end being represented by suspiciousness, mistrust, and self-consciousness and the severe end represented by delusions of persecution often involving hallucinatory experiences (Fenigstein 1996; Whaley 1998). Both mentally ill patients and normal persons have these types of paranoid tendencies, and the difference between them is a matter of degree or severity (Fenigstein 1996).

Whether a person recovers from a mental illness depends more on the diagnosis (e.g., paranoid personality disorder versus schizophrenia) than on the presence of paranoid symptoms. The notion “once paranoid—always paranoid” is not correct; people with paranoid conditions can recover (Retterstol 1991). Finally, the types of cultural experiences that people have may influence whether they exhibit paranoid behaviors.

Immigrants are at increased risk for developing paranoid responses (Kendler 1982). Social groups that have been oppressed or discriminated against such as African Americans also develop paranoid-type coping responses (Whaley 1998). The social and psychological theories of paranoia provide some insight into why this may be the case (Bentall et al. 2001; Marcus 1994; Mirowsky 1985).

Under these circumstances, the responses to real threats in the environment or adjustment to new experiences may appear similar to conditions of clinical paranoia, but these expressions often are normative and not pathological. Understanding that paranoia falls on a continuum from mild to severe, as opposed to a symptom that is either present or absent, allows us to appreciate that just because
someone is paranoid does not always mean that the person’s reaction is sign of mental illness.

PARADO

Parado is a Brazilian Portuguese term that translates as the color “brown.” It is an official census category used by the Brazilian Institute of Geography and Statistics (IBGE) to refer to all individuals who either self-identify or have been classified by interviewers as not “white” (branco) and not “black” (preto). It is a term that is not typically heard in speech or social interactions. Parado is an umbrella term that can include all individuals of mixed or multiracial ancestry. It is also a synonym for the term moreno, a racially ambiguous term that can refer to all individuals who have black or dark brown hair. Self-identification as pardo can reflect ancestry, culture, wealth, education, and socialization.

Parado is a term used by individuals to “whiten” or “darken” themselves when self-reporting on government census forms. France Winfield Twine (1998) has referred to this practice as “white inflation.” Parado is a racially ambiguous term that can be employed by dark-skinned individuals of visible or predominant African ancestry who possess forms of educational, social, or economic capital to avoid being classified as black (preto). The term pardo can also be used by all individuals of predominant or exclusive European ancestry to “darken” themselves. Consequently, individuals who would otherwise be classified as white based on ancestry or appearance but who possess little or no education, wealth, or social capital may self-identify as pardo rather than as blanco (white).

Terms that indicate color or race have been employed on the Brazilian census since 1940. In 1970 the Brazilian military decided that race was not statistically meaningful, so data related to color or race was not reported for this year. In contrast to the United States and South Africa, the criteria for inclusion in specific racial or color categories has not been legally defined in Brazil. This absence of legal classifications to precisely define race in Brazil facilitates discrepancies between how individuals are classified by appearance and how they may self-identify by race or color on the census and how others would racially classify them in local communities. In statistical analyses of the Brazilian national surveys that involve the self-reporting of race, U.S. sociologist Edward Telles (2002) found that consistency in racial classification varies from 20 to 100 percent depending on age, level of education, sex, and local racial composition. Inclusion in the category pardo is based on a combination of physical characteristics such as hair texture, nose shape, lip size and shape, and skin color, as well as achieved social characteristics such as education, occupation, and wealth.

PARENT-CHILD RELATIONSHIPS

Of all the interpersonal relationships humans develop across their life spans, none is more enduring or important than the parent-child relationship. The nature of the parent-child relationship is a primary factor underlying one’s personality, social, and cognitive development. Although there is little debate among family researchers regarding the importance of the parent-child relationship to later adult life, the attributes of a good parent-child relationship are still debated.

HISTORICAL VIEW OF PARENT-CHILD RELATIONSHIP RESEARCH

Throughout most of human history, parents have been concerned primarily with their children internalizing parental values and cultural norms. Thus, parenting was heavily focused on teaching children to be obedient to parental authority and the social and religious order through strict discipline and harsh punishments for disobedience. Most parent-child relationship research has focused on explaining the ways in which parents achieve these goals.

Behaviorists in the early part of the twentieth century argued that children learn how to behave in a culturally normative way through a series of punishments for unwanted behaviors and rewards for desired behaviors. These reinforcers were posited to lead to the development of behavioral habits in children. The major behaviorists of the time instructed parents not to show too much affection to children because they would develop habits of dependence and weakness. Behaviorists admonished parents who did not maintain firm control and a strict regimen of rules and structure.

Many schools of thought emerged that directly challenged these ideas of emotional distance and harsh punishment. For example, psychodynamic theory was based on the idea that children are born with innate drives and impulses for pleasure and self-fulfillment that may conflict with parental goals. Psychoanalysts suggested that parents learn to channel the energy from children’s unmet desires instead of repressing them. This led to the idea that parents should be less rigid, more accepting of children’s behavior, and emotionally available to children.

Based primarily on psychodynamic thought, Benjamin Spock (1903–1998) wrote the most influential parenting book in history, The Common Sense Book of Baby and Child Care (1945). In it, Spock advocated unconditional love, allowing children freedom to explore their surroundings, and limited use of parental authority. Spock, as well as other psychodynamic theorists, stressed increasing disciplinary reasoning and reducing parental power assertions such as spanking.

The research by Kurt Lewin (1890–1947) in the 1930s on group atmospheres was also influential to later ideas of effective parenting. In one of the most important studies, Lewin and colleagues examined the effects of autocratic, laissez-faire, and democratic leadership styles on preadolescent boys’ motivation and behavior. Autocratic leaders were trained to have a rigid structure in which they made all the decisions with little input from group members. Laissez-faire leaders were trained to not provide any structure or direction: The boys had complete freedom to work on their group projects as they saw fit. The democratic leaders were taught to provide structure, make suggestions, and list the goals, but seek input from the boys for most decisions. The results showed that the boys in the democratic group were more motivated and more cooperative, they produced a better final project, and they were more likely to work in a constructive manner when the leader left the room. The boys in the autocratic group produced an adequate final project, but when the leader left the room, chaos ensued. Those in the laissez-faire group produced the worst group project and displayed little interaction or cooperation.

Alfred Baldwin later applied these ideas to parents in the 1940s. In a longitudinal study, Baldwin found that parents he described as emotionally warm and who allowed their children a great deal of freedom had children with the best intellectual development. He argued that emotionally detached, authoritarian parenting was detrimental to children. Separate research into the authoritarian personality around this same time echoed these same concerns.
Parent-Child Relationships

Probably the most ardent opponents of the behaviorist approach to child rearing were the attachment theorists. Based on ethology, cybernetics, and psychodynamic principles, the groundbreaking theory developed by John Bowlby (1907–1990) and Mary Ainsworth (1913–1999) in the 1950s and 1960s made it explicitly clear that the best parent-child relationship is one in which there is mutual trust, respect, and an emotional bond. Furthermore, the attachment theorists argued that a mother's degree of responsiveness to her infant's needs and demands dictated the nature of the relationship. Highly responsive mothers tended to have infants who formed secure attachments with them. Less responsive mothers tended to have infants with ambivalent, avoidant, or disorganized attachments. A large body of research has shown that those with secure attachments to their primary caregivers tend to have better relationships with others, perform better in school, and are on the whole better adjusted than those with nonsecure attachments.

These different strands of research and theory on authoritarian parenting, psychodynamic theory, attachment theory, and other influential work in humanistic psychology all came to the same basic conclusion—the best parents are emotionally responsive to their children's needs and desires. This new trend in parenting led to the common belief that parents should be less concerned with discipline and child obedience and instead focus on the emotional climate of the relationship, accepting children for who they are, and not stifling their individuality. Although Spock and other psychodynamic theorists warned against spoiling children by avoiding disciplinary encounters and even picking up crying infants too much, and Lewin clearly warned against laissez-faire leaders, many in the general public took this to mean that punishment should give way to unconditional acceptance of child behavior.

This new focus on parental responsiveness and child freedom was in stark contrast to the behaviorist and religious fundamentalist focus on structure, order, and firm discipline. At the heart of this controversy were differing socialization goals. The authoritarian's goals were to have children comply with rules of existing social structures, as well as develop an emotional resiliency that would allow them to handle the challenges of life. Those who focused on parental responsiveness were more concerned with developing children's self-esteem and agency, as well as their cognitive development. Thus, they were fearful of stifling children's potential, whereas authoritarians were fearful of creating emotionally fragile and disobedient children. The political controversies surrounding these opposing views remain as virulent today as ever. However, the influential research on parenting styles by Diana Baumrind and similar models have helped to rectify much of the controversy in mainstream research.

PARENTING STYLES

Probably the most influential research-based parenting theory to date, Baumrind's authoritative model revolutionized the study of parenting when it was first proposed in the 1960s. Based on several studies, principles from behaviorism, psychodynamic theory, attachment theory, Lewin's leadership styles, and critical theoretical contributions from Eleanor Maccoby and John Martin (1983), Baumrind argued that there were four dispositional parenting styles, distinguished by their levels of parental demandingness and parental responsiveness.

According to Baumrind, parental demandingness refers to the degree to which parents facilitate structure in their children's lives, have control of the parent-child relationship, monitor children's behavior and whereabouts, use firm and consistent discipline, set high maturity demands for their children, and are willing to confront noncompliance by children. Based on concepts from attachment theory and psychodynamic theory, Baumrind defined parental responsiveness as the degree to which parents are warm, emotionally connected, and supportive of their children, as well as the amount of freedom and decision-making they allow children, their use of disciplinary reasoning, and their tendency to acquiesce to their children's needs and demands. Baumrind examined both major parenting dimensions simultaneously in defining the authoritarian, permissive, authoritative, and neglectful parenting styles.

Authoritarian parents are defined as being high on demandingness but low on responsiveness. Thus, authoritarian parents attempt to maintain firm parental control by confronting disobedience and restricting the amount of decision-making and general freedom a child has. Authoritarian parents do not usually reason with children or explain the rules, believing that a child should accept the rules without necessarily understanding them. Many have equated this style with certain behaviorist and religious fundamentalist views of parenting.

Permissive parents represent the antithesis of the authoritarian parents. They are low on demandingness and high on responsiveness. They attempt to be emotionally connected and have a warm relationship with their children, and they tend to be accepting of children's impulses and behaviors. Permissive parents also assert very little direct power to get their children to comply with their authority. Instead of direct confrontation, permissive parents often use various forms of psychological control as a means of getting their children to comply. Many have equated the permissive style with Spock's model of optimal parenting.

Authoritative parents essentially combine the best attributes of the authoritarian and permissive parenting ideas. They are high on both demandingness and respon-
siveness. They value independence in their children, but maintain firm control. Authoritative parents attempt to achieve the goals of behavioral compliance as well as psychological autonomy and agency by judiciously allowing freedom and decision-making in their children, and by giving them age-appropriate maturity demands and structure.

Neglectful parents are low on both demandingness and responsiveness, and they have chaotic and dysfunctional relationships with their children. Whereas the other parenting styles develop primarily from parents’ child-rearing goals and philosophy about what is best for children, the neglectful parents’ behavior is more a consequence of social circumstances than of philosophy. Neglectful parents tend to have the most children, the least income and education, and more mental health problems than other parents. Consequently, most of their parenting can be explained by dire social circumstances that prevent them from fulfilling their parenting duties.

As Baumrind predicted, European American youth with authoritative parents are more competent, well-adjusted, and high achieving, and less likely to use illicit drugs or engage in risky behaviors compared to those with nonauthoritative parents. In authoritarian homes, boys tend to be aggressive, and girls tend to be low in independence and dominance. Those with permissive parents tend to have problems with self-confidence, impulse control, and achievement. Not surprisingly, those with neglectful parents are at risk for virtually every negative outcome researchers have measured.

CULTURAL DIFFERENCES IN PARENTING STYLES

The research on parenting styles has shed much light on the most effective parenting strategies for European American youth, but the research on other groups is less clear. For instance, European Americans are more likely to have authoritative parents than Asian Americans, and Asian Americans are more likely than European Americans to have authoritarian parents, even though Asian Americans have higher overall academic achievement. Furthermore, some studies in the 1980s and early 1990s found no relation between parenting style and African American youth’s academic achievement. Others found that authoritarian parenting was not as detrimental to Asian American and African American youth as it was for European American youth.

Based on these findings, many suggested that the effects of parenting styles could only be understood in a specific cultural context. Often referred to as the “cultural specific model,” its proponents argue that African American youth may do better with authoritarian parenting because firm parental control is adaptive in the more dangerous inner cities. Similarly, Ruth Chao (1994) proposed the idea that Baumrind’s authoritative model was not a good description of the optimal parenting strategies for Asian American youth because it did not take into consideration the important cultural traits of filial piety, communalism, or other beliefs about expressions of emotion. The basic premise of the cultural specific approach to parenting styles is that the cultural context gives parenting behaviors meaning, so it is not the specific behaviors that matter, but the meaning that youth ascribe to the behaviors.

Counter to this perspective, the cultural equivalence model suggests that the effects of parenting styles are consistent across cultural groups. According to this model, all children, regardless of their ethnic background, gender, or other demographic factors, have the need for warmth, support, connection to others, structure, and autonomy. Consequently, the authoritative parenting practices such as reasonable behavioral control, provisions of emotional support and warmth, and psychological autonomy are important for all children. More recent studies in Asian countries and with African Americans lend support to this idea, finding that those Asian and African American youth with authoritative parents perform better in school and in other areas compared to those with other types of parents.

In conclusion, the study of parent-child relationships has changed dramatically since the beginning of the twentieth century, but many of the same controversies remain. Ultimately, the parenting goals of the authoritarian and the permissive groups are both desirable. Modern parents must find a balance between getting children to conform to parental authority and control their impulses and encouraging them to develop a sense of independence, agency, and critical thinking abilities. However, the empirical evidence is strikingly clear: Both the traditional authoritarian and more modern permissive methods for achieving those goals are limited. A combination of demandingness and responsiveness is best for achieving most pro-social parental goals. Although differences among cultural groups might lead to some variation in effective strategies for rearing children, given children’s universal needs for both affection and direction, authoritative parenting is most likely an optimal strategy for rearing all children.

PARENTHOOD, TRANSITION TO

In many cultures, the transition to parenthood takes place within a traditional marital relationship: When a woman becomes pregnant, she and her husband (or significant other) begin to prepare for the arrival of their new baby. Different cultures and ethnic groups sanction different means and timetables for such preparations, and evolving technologies and changing social norms have diversified the family structure. First-time parents may be single or attached to a same-sex partner; they may be adopting or conceiving using various reproductive technologies or with the help of a surrogate mother. However the child arrives and whatever the parents’ age, family structure, socioeconomic status, or ethnicity, new parents face a complex and vital transition into a novel, challenging, and ultimately rewarding life role.

Defining this new role and identifying the principal factors that contribute to a smooth transition can be elusive. Family-systems models identify multiple influences on the adaptation to parenting, including an individual’s biological, psychological, and sociological characteristics and those of family members, as well as the relationship between the new parents, between the parents and their extended families, and between the parents and the child. Levels of anxiety or confidence, for example, might be influenced by the new parents’ culture, their own parents’ parenting styles, and their infant’s temperament.

Social support from partners and friends appears to be one key variable in the successful transition to parenthood, particularly for new mothers. New parents must adjust not only to a set of novel responsibilities pertaining to child care, but also to challenges to many aspects of their personality and intelligence, including self-efficacy and personal control, patience and understanding, and problem solving and decision-making. The type of social support available to new parents frequently reflects the contributions of their own families as much as their community and culture. Social support systems function as critical sources of information about parenting and child development.

Parents generally begin the search for information long before the arrival of a baby; information gathering on labor and child care tends to increase in the second and third trimesters of pregnancy. New parents often struggle with anxiety or postpartum depression; education and strong parent partnerships both help to alleviate parental stress. Gathering information about parenting and child development helps new parents gain an understanding of “normal” development and set realistic expectations for their children. Understanding child development also helps improve parent performance and augments parental satisfaction. Information gathering helps individuals prepare psychologically for the coming responsibilities of child care and define their identity as a parent.

Relationships between partners change with the arrival of a child: While satisfaction with the level of emotional support between parents often improves, general marital satisfaction usually declines following a birth. Couples who adopt children rather than bear biological children suffer less deterioration in marital satisfaction, perhaps due in part to the additional preparation and planning that accompanies adoption. Satisfaction with participation in and effectiveness of child care increases as men become comfortable in the role of father and a healthy co-parent partnership develops.
In some couples, maternal and paternal roles follow traditional patterns. This is less common if both parents are employed, and these couples need to arrive at a stable division of labor in the family. Not all parents make the transition well. Adolescent parents in particular have not fully matured themselves and are less likely to have a realistic grasp of child development, further complicating their already demanding transition to parenthood.

Historically, evaluations of parenting have been biased toward the positives of parenthood, sometimes leaving aside the realities of parental feelings of guilt and failure after (inevitable) negative parenting experiences. Parents must continually adjust their parenting; as a child develops, the parent–child relationship changes continually as well. Acknowledging parenthood’s challenges and negative aspects signifies a positive change in social attitudes about parenthood. Only full awareness allows adults to prepare properly for the transition.

PARENTING STYLES

Parenting or childrearing styles are parents’ characteristic, consistent manner of interacting with their children across a wide range of everyday situations. Research on parenting styles has demonstrated their influence on children’s developmental outcomes, including academic skills and achievement, aggression, altruism, delinquency, emotion regulation and understanding, moral internalization, motivation, peer relations, self-esteem, social skills and adjustment, substance abuse, and mental health.

CLASSIFICATION SYSTEMS

Researchers have developed three primary ways of classifying parenting styles. In the late 1950s and early 1960s, Earl Schaefer and Wesley Becker proposed circumplex models of parenting. Their models have in common two independent dimensions proposed as important in understanding parenting style (see Figure 1). One dimension involves parents’ emotional or affectionate attitude toward the child; the other, parents’ exertion of control over the child’s behavior. Because each dimension forms a continuous measure, parents’ individual styles may be mapped anywhere within the circumplex.

The system developed by Jeanne Humphries Block in the mid-1960s is multifaceted. Block noted that the structure of parenting or childrearing styles may vary across groups of parents; thus, defining a universal set of parenting dimensions may be neither desirable nor possible. Nonetheless, like Schaefer and Becker, Block’s work has identified dimensions related to parental control or restriction of children’s behavior, and to parents’ emotional attitude or responsiveness to the child. Additionally, Block noted that the degree to which parents find childrearing to be satisfying and are involved with their child, among other dimensions, may be important in understanding parenting styles and their influence on children’s outcomes. In the late 1980s, William Roberts and Janet Strayer conducted further work with Block’s measurement system that suggested five dimensions: (1) parents’ warmth and closeness rather than coolness and distance; (2) parental strictness and use of punishment; (3) parental encouragement of children’s boldness and maturity; (4) parents’ enjoyment of and involvement in parenting; and (5) parents’ encouragement or discouragement of children’s emotional expressions. Composition of these dimensions differed somewhat between mothers and fathers.

In the late 1960s, Diana Baumrind formulated a typology including three distinct parenting styles: authoritative, authoritarian, and permissive. These parenting styles vary according to parents’ demand that their children meet standards for behavior and their responsiveness to their children’s needs. Authoritative parents are high in both demand and responsiveness. They communicate to their children about expectations and standards in a warm and responsive manner. Authoritarian parents are highly demanding but are neither warm nor responsive to their children’s behavior. Their expectations and demands are communicated with little to no rationale or warmth. Permissive parents are moderate in responsiveness and warmth and low in demand, tending to accept children’s
impulses. There is an absence of parental enforcement of expectations or standards for children’s behaviors.

In 1983 Eleanor Maccoby and John Martin integrated extant theory and research and proposed four parenting styles, differing along the two dimensions of control or demand and warmth or responsiveness that are held in common in all three preceding systems and incorporating parental involvement into those dimensions. Maccoby and Martin’s reconceptualization proposes three styles similar to Baumrind’s typology, and in addition a fourth style, uninvolved or neglectful parenting, which is characterized by both a low degree of parental demand that the child meet behavioral expectations and by low warmth and responsiveness to children’s needs (see Figure 1). These parents may appear distant and uninterested in their children, or may respond to children in a manner designed only to end children’s requests rather than to help their child develop. These four parenting styles are generally used.

**ASSESSMENT METHODS**

Parent and child self-report and naturalistic observations have been used to assess parenting style. Q sort tasks, in which parents or outside observers (i.e., researchers, teachers) divide a set of statements into piles according to how characteristic they are of the parents’ typical style, have been popular in measuring parenting or childrearing style because they may reduce some self-report or observer bias. One area of controversy in measurement is whether parents should be assigned to mutually exclusive categories (typological approach) or whether parents’ extent of using each parenting style or dimension (dimensional approach) should be measured. For example, using the typological approach, a parent would be described as authoritative if most of his or her parenting behaviors fit that style, even if he or she showed frequent authoritarian and occasional permissive behaviors. Using the dimensional approach, the same parent would receive scores for each parenting style, high for authoritative, moderate for authoritarian, and low for permissive, reflecting the extent to which they were used. In 1994 Laurence Steinberg and colleagues described the typological approach as most appropriate for assessing short-term child outcomes because parents’ predominant style is emphasized. Conversely, because the dimensional approach includes measurement of all parenting styles, in their 1989 work Wendy Grolnick and
Richard Ryan noted the advantage of investigating independent and joint effects of parenting styles on children’s outcomes.

RELATIONS TO CHILDREN’S DEVELOPMENTAL OUTCOMES

Parenting styles are often used in investigating diverse developmental outcomes, such as academic competence, achievement, self-esteem, aggression, delinquency and substance abuse, moral reasoning, and social adjustment. Research suggests that authoritative parenting is conducive to optimal development. Specifically, children reared by authoritative parents demonstrate higher competence, achievement, social development, and mental health compared to those reared by authoritarian or permissive parents. Negative effects of authoritarian parenting on children’s outcomes include poorer self-esteem, social withdrawal, and low levels of conscience. Permissive parenting has been related to negative outcomes such as behavioral misconduct and substance abuse. The worst outcomes for children are associated with neglectful parenting. This lack of parenting is associated with delinquency, negative psychosocial development, and lower academic achievement. Longitudinal research by Steinberg and colleagues supports these concurrent associations such that children raised by authoritative parents continued to display positive developmental outcomes one year following measurement of parenting style, whereas those raised by neglectful or indifferent parents had further augmented negative outcomes.

From Baumrind’s framework, in authoritative homes children’s adaptive skills are developed through the open communication characteristic of parent-child interactions. Parents’ clear expectations for children’s behavior and responsiveness to children’s needs provide an environment that supports children’s development of academic and social competence. Authoritative parenting does seem to be robustly associated with positive outcomes across ethnically and socioeconomically diverse populations, though the strength of the association varies.

Less clear is whether permissive and authoritarian parenting styles have negative effects on children’s development in varying contexts. In 1981 Catherine Lewis questioned whether the positive outcomes associated with authoritative parenting were due to the combination of demand and responsiveness, or rather to the warm and caring parent-child relationship. When a parent-child relationship has few conflicts, and therefore there is little need for parents to exert control over children’s behavior, permissive parenting might be as effective as authoritative parenting. Indeed, from an attribution theory framework, parents’ absence of controlling children’s behavior would be expected to lead to children’s internalization of behaviors and values. Research in the United States and in China in the 1990s and 2000s suggested that the combination of greater parental warmth or support and less parental control or punishment is related concurrently or retrospectively to positive outcomes such as self-esteem, prosocial behavior, socioemotional skills, and family harmony.

Lewis proposed that the firm but not punitive control characteristic of authoritative parenting might be more reflective of children’s willingness to obey than of parents’ style. In 1994 Joan Grusec developed a theoretical model that elaborated children’s role in accurately perceiving and choosing to accept or reject their parents’ communication of behavioral standards through disciplinary practices and parenting style. Few researchers have investigated such bidirectional child effects on parenting styles. An exception is Janet Strayer and William Roberts’s 2004 research, in which they statistically tested whether children’s anger elicited parents’ control and lack of warmth and found greater evidence for parenting style leading to children’s anger and thereby impacting children’s empathy.

Some research indicates a lack of negative or even positive outcomes for children whose parents are highly strict and authoritarian, depending on the family’s ethnicity (e.g., African American, Clark et al. 2002; Palestinian-Arab, Dwairy 2004). In 2004 Enrique Varela and colleagues found that it was not ethnicity per se (nor assimilation, socioeconomic status, or parental education), but rather ethnic minority status that was related to greater endorsement of authoritarian parenting by Mexican immigrant and Mexican American families living in the United States compared to both white, non-Hispanic families living in the United States and Mexican families living in Mexico. Varela and colleagues have called for research to examine ecological influences on parenting style and on the effects of parenting style on children’s outcomes.

Finally, reminiscent of Block’s perspective, some research suggests that additional or redefined parenting styles and dimensions may be necessary to understand parenting across-culturally. Filial piety and individual humility, which involve emphasizing family or group obligations, achievements, and interests over individual goals and expressions, are two parenting values that have been identified in Hong Kong and mainland Chinese families. Peixia Wu and colleagues (2002) cautioned that, despite seeming similarities between Chinese parenting dimensions such as directiveness and maternal involvement and the demand and responsiveness characteristic of authoritative parenting, the meaning of the dimensions and their relations to one another seem to vary considerably between Chinese and American mothers. Thus, although parenting style may provide a useful framework for under-
standing developmental outcomes, it is critical to consider the meaning of parenting practices and styles within the family’s cultural context.

PARETO, VILFREDO
1848–1923

Vilfredo Pareto was born in Paris on July 15, 1848, the son of Raffaele (a marquis originally from Genoa, republican political exile, and hydraulic engineer) and Marie Metenier, the daughter of a winegrower from Moulins, a small city in the department of Allier in central France. Vilfredo was therefore perfectly Italian-French bilingual. He could also read English but did not know any other modern language, although he had a good knowledge of ancient Greek and Latin (and their respective cultures).

He studied in Turin, where in 1867 he obtained a degree in mathematics, and in 1870 a degree in engineering. From his university studies he derived not only an up-to-date mathematical and technological preparation but also his scientific method: the logical-experimental method. It is likely that he acquired this method from Dutch physiologist Jakob Moleschott (who in that period was teaching at the University of Turin), and then refined it by studying John Stuart Mill’s System of Logic in its French edition (1866).

Pareto thought that the explanation (that is, the theoretical reproduction) of reality can never be perfect but can always be improved by drawing the hypotheses of the theory from the observation of reality, by developing them with the help of mathematics, and by obtaining in this way some propositions that must then be compared with reality (through statistics and history). From the discrepancies that one inevitably finds, one can deduce some refinements for the starting hypotheses, and so on.

From 1873 until 1890, Pareto managed one of the first Italian ironworks, situated in San Giovanni Valdarno near Florence. After resigning in 1890 because of differences with the owners, he devoted himself to journalism as a vehicle for his views in favor of pacifism and free trade.

Through Maffeo Pantaleoni and above all Léon Walras, he became interested in mathematical economics, which he initially intended to use to provide economic liberalism with new theoretical foundations. Pareto was offered the chair of political economics at the University of Lausanne, where he replaced Walras, who had resigned for health reasons. There he taught, albeit with increasing irregularity, from May 12, 1893, to June 9, 1909. From Walras he only took the concept of General Economic Equilibrium (GEE) because of its methodological property of encompassing the whole of economic phenomena. He developed it by applying it to reality and above all by giving it a new foundation in the theory of choice, which seemed to him more compatible with his methodology than the theory of utility, a concept that could not be easily measured and was therefore unbearably metaphysical.

In the same framework Pareto places his well-known definition of economic optimum as an allocation of resources such that if, as one moves away from it, the opHELIMITY, or economic satisfaction, of at least one individual increases and the opHELIMITY of at least one other individual decreases. The sources of this definition are
Walras's demonstration of the optimality of free competition and some criticisms by Pantaleoni and Enrico Barone about a first tentative Pareto’s treatment of the subject.

The failure of European economic liberalism at the end of the nineteenth century did nevertheless reinforce his idea that economic theory was unable to explain the whole of social reality. Many more concepts were required for that, and Pareto took them from sociology. In this way he integrated GEE in a general social equilibrium whose main elements, alongside interests, are: passions (which he called residues); the diversity of human beings, which generates the division of every society into a majority of dominated people and a minority of dominating people, that is, the elite, with the elites following one another in power in rather rapid succession; and derivations (that is, the pseudological motivations that human beings give for actions—and they are the majority of all actions—that are in fact only inspired by passions). The main criticisms of Pareto regard the static nature of his systems of general (economic and sociological) equilibrium, and his idea that human nature cannot be modified. In the last months of his life Pareto sympathized with fascism, as many Italian liberals did at the time, since in it he saw the timely restorer of Italian public order, which had been disrupted by the local supporters of bolshevism. On the other hand, he noticed and condemned the first authoritative trends of Mussolini’s regime.

Pareto died in Céligny, Canton Geneva, Switzerland, on August 19, 1923.

PARETO OPTIMUM

In further developing French economist Léon Walras’s 1874 demonstration of the optimality of free competition, at first Italian economist Vilfredo Pareto studied the problem of optimal allocation of resources in terms of maximization of utility for a representative agent, which he described in his 1892 article “Considerazioni sui principi fondamentali dell’economia politica pura.” In a later article titled “Il massimo di utilità dato dalla libera concorrenza.” (1894a), he re-analysed the question by determining the production coefficients that maximize the utility of a collectivistic society and demonstrated that they are exactly those of free competition (this is the real origin of the story of the second theorem of economic welfare). It was only at an even later stage, and as a consequence of some criticisms by Italian economists Maffeo Pantaleoni and Enrico Barone, that this theorem was redemonstrated by Pareto in 1894 and 1909. To reconfirm his theorem, Pareto started from the hypothesis of the incomparability of individual ophelimites, in flagrant contrast with his methodological position according to which every science—and therefore economics as well—is a science of averages. From this there directly ensues the proposition that an allocation of resources is optimal (i.e., it is a pareto optimal point), if, as one moves away from it, the ophelimity of at least one individual increases and the ophelimity of at least one other individual decreases. On the other hand, this proposition cannot obviously be made operational from the point of view of economic policy, because the entire availability of resources of a society can be allocated in an infinite number of Pareto optimal points (described by the contract curve), from which the maximum maximorum (i.e., the best of the pareto optimal points) cannot therefore be extracted. Pareto more or less understood this difficulty and resolved it by stating in a 1913 article that if one wishes to give indications in terms of economic policy, one has to move into the realm of sociology, where the optimal allocation of resources can be univocally identified starting from a comparison between personal ophelimites arbitrarily carried out by the government.

The question of the economic unclassifiability of Pareto optimal points was authoritatively tackled in later years. As a solution, John Hicks and Nicholas Kaldor both published articles in 1939 that proposed a criterion of compensation that is conceptually similar to Pareto's sociological criterion. Abram Bergson in his 1938 article “A Reformulation of Certain Aspects of Welfare Economics” and Paul Anthony Samuelson in his 1947 publication Foundations of Economic Analysis attempted to solve the problem by maximizing a social well-being function that was constructed, however, starting from cardinal individ-
ual functions of utility made comparable by resorting to value judgments.

While giving rise to outstanding formal analyses by such economists as Aldo Montesano (1990), Maurice Allais (1989), and Mark Blaug (1992), the subsequent literature developed around the theme of the either positive or normative nature of the Pareto optimum. While P. Hennipmann in his 1976 article “Pareto Optimality: Value Judgement or Analytical Tool” and G. C. Archibald in his 1959 article “Welfare Economics, Ethics, and Essentialism” defended the thesis that Pareto’s postulates do not reflect value judgments, Alan T. Peacock and Charles K. Rowley, in their 1972 and 1974 articles, weakened it by differentiating between economic liberalism and Pareto optimality, even though they attempted to portray the latter as a simple tool of economic reasoning. The normative thesis was taken to its extreme and—considering Pareto’s unwavering political-intellectual militancy—paradoxical consequences by Amartya Sen in 1970 and 1971 in articles where he demonstrated that in order to be logically consistent social choice cannot at the same time be liberal (respect of other people’s preferences, once one’s own have been reaffirmed) and Pareetian (incomparability of individual preferences and therefore necessary unanimity of social choices). Sen has been criticized in the literature for his too narrow definition of liberalism. By relaxing it, the compatibility between Pareto’s principle and liberalism would be restored. On the other hand, it should be pointed out that no ordinalistic theory of economic welfare based on a definition different from Pareto’s has yet been developed.

PARK, ROBERT E. 1864–1944

The American sociologist Robert Ezra Park was a leading figure in the “Chicago school” of sociology. He was born February 14, 1864 in Harveyville, Pennsylvania. His
mother, Theodosia Warner, was a schoolteacher and his father, Hiram Asa Park, was a soldier in the Union army. Soon after the Civil War the family moved to Red Wing, Minnesota, where Park grew up.

Park attended the University of Michigan and received a Ph.B. in philosophy in 1887, studying under the young John Dewey (1859–1952). From 1887 until 1898 he was a reporter on daily newspapers in Minneapolis, Detroit, Denver, New York, and Chicago. In 1894 Park married Clara Cahill, and they had four children: Edward, Theodosia, Robert, Jr., and Margaret (Raushenbush 1979).

In 1899 Park entered Harvard University, where he studied under William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with Georg Simmel (1858–1918) and took the only formal course on sociology he ever had. He completed his Ph.D. in 1904 at Heidelberg with his dissertation, “Masse und Publikum” (The Crowd and the Public). He returned to Harvard for a year, but soon became bored with academic life and accepted the position of secretary of the Congo Reform Association. He later met Booker T. Washington (1856–1915) and Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916). He then took his family to Germany, where he studied with William James (1842–1910) and Josiah Royce (1855–1916).

At the invitation of W. I. Thomas (1863–1947), Park joined the faculty at the University of Chicago in 1914 and remained there until he retired in 1929. Between 1929 and 1932 he traveled extensively, researching race relations in other countries and teaching. He was a guest professor at Yenching University in Peking and at the University of Hawaii. From 1936 until his death in 1944 he lectured at Fisk University in Nashville, Tennesse (Hughes 1968).

Park was not a prolific writer, but he produced several books and numerous articles. His articles have been published in three volumes by his students as The Collected Papers of Robert Ezra Park, vol. 1: Race and Culture (1950), vol. 2: Human Communities: The City and Human Ecology (1952), and vol. 3: Societies (1955). Perhaps his most influential publication was the pathbreaking Introduction to the Science of Sociology, published with Ernest W. Burgess in 1921, which has been described as the most influential sociological textbook ever produced in the United States (Martindale 1960; Coser 1971).

In Park's view, society is best seen as the interactions of individuals controlled by traditions and norms. Park was keenly interested in social psychology, and his favorite topics were collective behavior, news, race relations, cities, and human ecology (Raushenbush 1979). Park defined sociology as "the science of collective behavior," which suggests the need for analysis of social structures with the study of more fluid social processes (Coser 1971, p. 358). These processes are divided into four major categories: competition, conflict, accommodation, and assimilation. Park held that "competition is the elementary universal and fundamental form of social interaction" (Park and Burgess 1921, p. 507). It is as universal and continuous in human society as it is in nature, and it assigns persons their position in the division of labor. Conflict is intermittent and personal. Competition determines the position of the individual in the community; conflict fixes his place in society (Coser 1971, p. 359). Accommodation is a cessation of conflict that is fragile and easily upset. Assimilation "is a process of interpenetration and fusion in which persons and groups acquire the memories, sentiments, and attitudes of other persons and groups, and, by sharing their experiences and history, are incorporated with them in a common culture" (Park and Burgess 1921, p. 735). Then when assimilation is achieved it does not mean that individual differences are eliminated or that competition and conflict end, but that there is enough unity of experience so that a "community of purpose and action can emerge" (Coser 1971, p. 360). Social distance refers to "the degree of intimacy that prevails between groups and individuals. The degree of intimacy measures the influence which each has over the other" (Park 1950, p. 357). The greater the social distance between individuals and groups, the less they influence each other.

Although Park's theory fit with the prevailing assimilationist view of his time, there are several criticisms of his race-relations cycle: (1) Park did not set a time frame for the completion of the assimilation process—making it essentially untestable; (2) Park could not cite any racial group that had passed through all four stages of his cycle—instead, he and other assimilation theorists explained the lack of assimilation as the result of interference in the process, resulting in a tautological theory that can neither be proved nor disproved; (3) Park did not describe the assimilation process in much detail (Healey 2007; Parrillo 2005).

Park described sociology as the "abstract science of human nature and experience" that included the "applied science" of his four social process to analyze "those modifications in human beings that are due to the human environment."

The same social forces which are found organized in public opinion, in religious symbols, in social conversation, in fashion, and in science ... are constantly recreating the old order, making new heroes, overthrowing old gods, creating new myths, and imposing new ideals. And this is the nature of the cultural process of which sociology is a description and an explanation (Park and Burgess 1921, quoted in Raushenbush 1979, p. 82).
Park’s sociology “always focused analytical attention on those processes or situations which foster the emergence of novel forms that upset or render obsolete previous adjustments and accommodations” (Coser 1971, p. 366).

Although Park has sometimes been accused of making racist remarks, his interest in the problem of race relations stems from a desire for a deeper understanding of the human situation. In a letter to Horace R. Cayton, another Chicago school sociologist, Park elaborated on his work with Negroes, demonstrating his broader analytical views of the problems involved:

Democracy is not something that some people in a country can have and others not have, something to be shared and divided like a pie—some getting a small and some getting a large piece. Democracy is an integral thing. If any part of the country doesn’t have it, the rest of the country doesn’t have it (quoted in Raushenbush 1979, p. 177).

Park stimulated his students to learn from their own experiences and observations: “Park’s teaching always gave the sense of something in the making” (Raushenbush 1979, p. 184).

There is no better testimony to the impact of Park’s teaching than the imposing roster of his students. Everett C. Hughes, Herbert Blumer, Stuart Queen, Leonard Cottrell, Edward Reuter, Robert Faris, Louis Wirth, and E. Franklin Frazier all became presidents of the American Sociological Society. Helen McGill Hughes, John Dollard, Robert Redfield, Ernest Hiler, Clifford Shaw, Willard Waller, Walter C. Reckless, Joseph Lohman and many other students of Park became leading social scientists. It is hard to imagine the field of sociology without the contribution of the cohort of gifted men whom Park trained at Chicago. What higher tribute can be paid to a teacher? (Coser 1971, p. 372).

Charles S. Johnson, one of Park’s students, noted that “his mind never ceased to work with ideas and he had not lost his zest for life and work and the still uncharted frontiers of human behavior even when, in his final illness, he could no longer speak” (Raushenbush 1979, p. 176). Park died at his home on February 7, 1944, seven days before his eightieth birthday.

**PARK SCHOOL, THE**

The concept of a school includes having “a central figure around whom the group is located, who is an inspiring and effective leader, whose school it essentially is, and without whom the school eventually begins to break-up” (Harvey 1987, p. 3). Robert Ezra Park (1864–1944) was that essential figure during his tenure in the Sociology Department at the University of Chicago. Park had been a newspaper journalist prior to becoming a sociologist. He brought the practice of immersing oneself into a situation as a participant observant to his new field and taught his students to do the same (Harvey 1987). A great deal of Park’s work was undertaken in conjunction with Ernest W. Burgess (1886–1966), Park’s colleague and friend. Park’s sociology, which includes his reliance upon field research as well as much of the novel theory that he and Burgess espoused coupled with Park’s ability to attract quality graduate students, is often referred to as the Park school of thought or the “Park School.”

**HUMAN ECOLOGY**

One of Park and Burgess’s major contributions to sociology is the use of ecology in the study of human groups. Borrowing from animal ecology and economics, Park
hypothesized that, much like plant and animal life, human groups carve out niches for themselves based on competition for space (Park 1950). For example, key tenets of Burgess and Park's concentric zone theory are that businesses need a central location and that communities build around these business districts to form biotic or mutually interdependent relationships. Additionally, the zones are populated and repopulated via a cycle of invasion and succession much like that found in plant life (Coser 1971).

The social or moral order differentiates human and plant or animal negotiation of the ecological system. Human society is composed of both the biotic (interdependence) and the culture that encompasses the ability to communicate. Humans engage in collective action to create a society that is composed of a common will. Population, material culture, nonmaterial culture, and natural resources interact to create a social hierarchy or social order that maintains biotic balance and social equilibrium. Park's race relations theory is a human ecology theory that exemplifies social order in transition or social change (Park 1950).

Park posits that there is a cycle of events that repeats itself in every initial encounter or contact between racial groups. The cycle includes four stages: contact/conflict, competition, accommodation, and assimilation. He identified contact as the first stage, while other researchers use contact and conflict interchangeably (Park 1950). Although Park assumed that each minority group would eventually fully assimilate into the dominate group, he theorized that each group could possibly go through a series of accommodations first.

Borrowing from Georg Simmel and preceding Emory Bogardus's social distance scale, Park suggested that social distance is the level of intimacy experienced between diverse racial groups or the etiquette of knowing one's group's place in the social order (Coser 1971). Compromised social distance etiquette or conflict between groups for space and life's rewards disturbs the moral order or ecological equilibrium. Social change re-adjusts the balance in three stages: dissatisfaction, social unrest and mass movements, and finally a new accommodation (Coser 1971). The new accommodation, which is often assimilation, is a social change (Park 1950).

Through his students, Park's influence extends further than his individual contributions to the discipline. Eight of his students became president of the American Sociological Association. Many more of his students became leading sociologists and took Park's work in many directions (Harvey 1987). Clifford Shaw's work with concentric zone theory birthed theories of criminology of place as well as social disorganization theories; E. Franklin Frazier expounded on that line of research to develop sub-
culture theory; and Louis Wirth's research contributed to the foundation of twentieth-century urban sociology. Similarly, Park's critics span the generations as well.

CRITICS AND THE DECLINE OF THE SCHOOL
In her 1988 book, Mary Jo Deegan suggests that human ecology theory is a pathological marriage between sociology and Darwinism. Others posit that human ecology theory ignores the influence of the social environment and does not consider the impact of human diversity (Brown 2006). Park's contemporaries, including many University of Chicago sociology scholars, criticized his resistance to the use of quantitative methods (Harvey 1987). Although Chicago also always had quantifiers, Chicago never lived Park's qualitative reputation down. Despite the criticism, Park's retirement was a big factor in the decline of the department. No one else could inspire students like Park, nor was anyone else as devoted to their intellectual and research success as was Park (Harvey 1987). In addition, to outsiders, sociological research done at Chicago was the sociology of Chicago or the “Park School.” Without Park, the research ethos was lost. Finally, while Chicago would never dominate sociology again, no other department ever held the dominance that the University of Chicago held during Park's tenure (Harvey, 1987).

PARLIAMENT, UNITED KINGDOM
The United Kingdom Parliament has one of the longest histories of any representative assembly in the world and is often referred to, mistakenly, as the “mother of parliaments.” The modern U.K. parliament consists of representatives from the four countries of England, Northern Ireland, Scotland, and Wales and is located in the Palace
of Westminster in central London, England. Hence, it is commonly referred to as the Westminster parliament.

After the 2005 U.K. general election there were 646 elected members of Parliament: 529 representing English constituencies, 18 from Northern Ireland, 59 from Scotland, and 40 from Wales. The U.K. parliament is bicameral. In addition to the elected members who sit in the lower chamber, the House of Commons, there are also some 700 members of the upper chamber, the House of Lords, who are known as “peers.” The numerical composition of both houses of Parliament had been subject to change as a result of the constitutional reforms of the post-1997 Labour governments. The creation of a devoled parliament in Scotland in 1999, alongside representative assemblies in Northern Ireland and Wales, led to a reduction in the size of the House of Commons from 659 to 646 in 2005; whereas the abolition of hereditary peers, under the provisions of the House of Lords Act 1999, virtually halved the total membership of the upper chamber from 1295 to 695. After the implementation of this act, some 80 percent of the members of a new “interim House” were “life peers” who were appointed for their lifetimes, 4 percent were bishops or archbishops of the established Church of England, 4 percent were law lords, and 12 percent were “elected hereditary” peers. The 92 elected hereditary peers were to be removed after the second phase of reform, and the law lords and their associated judicial functions were to be removed upon the creation of a separate supreme court in 2008. Following the changes to the composition of the House of Lords, an independent public body, the House of Lords Appointment Commission, was established in May 2002 to scrutinize nominations made by political parties and to recommend nonpolitical appointees to the Queen. Formally, life peers are appointed by the monarch on the advice of the prime minister.

In addition to the two chambers—the Commons and the Lords—the monarch is also part of Parliament and, in fact, the legally precise institutional term for the body is the Crown-in-Parliament. Indeed, the history of the U.K. parliament reflects the changing relationships between monarch, political executive, and legislature, and between the constituent nations of the United Kingdom.

HISTORY

The origins of the English parliament can be traced back to the eleventh and twelfth centuries in the institutional forms of the Anglo-Saxon Witenagemot, a national assembly of freemen, and the medieval king’s court, the Curia Regis. In the thirteenth century, monarchs became more reliant for the consent and authorization of their policies, particularly taxation policies, upon intermittent meetings of the feudal magnates, the great ears and barons (who controlled private armies), the archbishops, bishops and abbots (who represented the church as the major landowner of the time), and eventually, between 1265 and 1295, representatives of urban citizens and commercial classes. In 1265 Simon de Montfort parliament (named after the most powerful baron) met for the first time in Westminster Hall, in the Royal Palace of Westminster. In 1295 the “model parliament,” summoned by King Edward I, extended the base of representation formally to members of the “Commons.” Initially representatives of the Commons were not allowed to speak in the presence of their more powerful feudal superiors and, for this reason, began to meet separately from the Lords, and after 1377 elected a “Speaker” to speak on their behalf to the monarch. Importantly, the principles of consent and representation were invoked at the time in support of, and not as a challenge to, strong monarchical (executive) government. Parliamentary government in Britain has historically been conceived, and functioned, as a means of legitimating executive power.

The inversion of the power relationship between the Crown and Parliament eventually came during the civil war in the seventeenth century and reflected a wider transformation of economic, social, and political forces in the English state. Attendant upon these wider economic and social transformations came institutional change. These changes found confirmation, eventually, in the Constitutional Settlement of 1689. After 1689 legal supremacy rested in Parliament rather than in any other state institution—whether monarch or law courts. The boundaries of legitimate state power were thus marked out. The subsequent history of parliamentary development in Britain (in 1707 the Act of Union merged the separate English and Scottish parliaments into a single parliament of Great Britain) saw Parliament retained at the center of the state but, inevitably, it was not to be sustained as the central institution of state decision making—which became focused upon the prime minister, cabinet, and executive.

MODERN FUNCTIONS

The U.K. parliament is a multifunctional institution. As a representative body Parliament has served the functions of providing consent, legitimation, and authorization for executive actions. Modern governments derive their authority from their majority party position within a democratically elected House of Commons. Conventionally government ministers are recruited primarily from the Commons, but may also be members of the Lords. Parliament serves, therefore, to recruit ministers and also to hold them accountable by requiring them to explain and defend their actions. A key role of Parliament, therefore, is to examine government policy and administration and to inform the public about what the government is...
doing and why. A variety of procedures are available to perform these scrutiny and informing functions: debates; questions; and committees—"standing committees" that process legislation and "select committees" that scrutinize and investigate executive actions more broadly. Although the U.K. parliament is a legislature, its primary legislative role is to scrutinize, amend, improve, and authorize laws proposed by the executive. Each house has a similar five-stage legislative process, and all laws have to be agreed by both houses. Although the Lords actively proposes and makes legislative amendments, ultimately, the final decision rests with the government in the House of Commons. Under the Parliament Act of 1949, if the Lords does not approve a bill it can only delay its passage into law for up to one year. Given the control of the majority party in the House of Commons, the average success rate of government proposals becoming law is some 95 percent. The final stage of the legislative process in Parliament is the royal assent, whereby legislation is accepted with the symbolic words "La Reyne le veult"—"the queen wills it." These words underline the continued significance of "the Crown-in-Parliament" and point to the institutional complexity of the United Kingdom as both a parliamentary democracy and a constitutional monarchy.

PARLIAMENTS AND PARLIAMENTARY SYSTEMS
Parliaments are representative institutions that link political decision makers with citizens affected by the decisions taken. Representative institutions have a variety of names in different countries—Parliament (a term usually associated with the United Kingdom and often adopted in its former colonies, for example, in Australia, Canada, and India); Congress (for example, the United States, Argentina, Brazil, China, Mexico); Assembly (for example, Cuba, Slovenia, and the Russian Federation); Cortes (Spain); Diet (Japan); Folketing (Denmark); Sejm (Poland); and Storting (Norway)—and are often subsumed under the generic term "legislature." In total, throughout the world in 2006, the Inter-Parliamentary Union listed 189 national parliaments with over 44,000 members. These ranged in size from the 2,980 members in the Chinese National People’s Congress to 15 members in the Parliament of the Tuvalu Islands in the South Pacific. Seventy-five parliaments were bicameral, having an upper house or a senate alongside a lower house or representative assembly. In addition, there are also a large number of regional or subnational parliaments, with seventy-four in western Europe, thirty in India, and fifty in the United States. At a supranational level the European Parliament, after January 1, 2007, had 785 members representing over 375 million voters from twenty-seven member states in the European Union.

Yet not all parliaments in the twenty-first century are democratic institutions—in the sense that their members are chosen through the processes of free and competitive elections. In 2006, the United Nations Development Programme identified only 140 countries in which competitive multiparty elections were held for national parliaments.

ORIGINS AND HISTORIC PRINCIPLES
The Icelandic Althingi has a claim to be the oldest parliament, as it met for the first time around 930 CE and served as a general assembly of the most powerful leaders, where legislative acts were made and justice was dispensed. Other parliaments emerged in Europe in the twelfth and thirteenth centuries, when monarchs convened meetings of representatives of the most powerful sections of feudal society to authorize specific royal policies and taxes. The English Parliament, the Spanish Cortes, the French States-General or Estates-General, and the Scandinavian parliaments all trace their roots back to such medieval advisory bodies. Although the subsequent institutional trajectories of these parliaments differed markedly, and while most parliaments were in abeyance for long periods, nonetheless, the principles of authorization and representation marked the common and continuing hallmarks of parliamentary institutions. By the beginning of the twentieth century most western European countries had parliamentary systems, and such systems proved to be resilient. Even those countries that endured authoritarian regimes at some stage in that century (Germany, Italy, Greece, Portugal, and Spain) subsequently reestablished parliamentary systems.
In their contemporary forms, parliaments still institutionalize the principles of representation and authorization, but now these ideas are normally associated also with the electoral principle and notions of accountability. In turn, elections and accountability invoke ideas of “representative and responsible” government—where decision makers are representative of those for whom decisions are to be made and are responsible to those affected by the decisions. In this sense, parliaments occupy pivotal institutional positions in the linkage between citizens and governors. Indeed, parliaments face in two directions: first, toward the “people,” the “represented,” or the “governed”; and, second, toward the “government” or the “political executive.” In this pivotal position, parliaments can be seen as part of an institutional nexus of government—as a “parliamentary system.”

PARLIAMENTARY SYSTEM

Like any other system, a parliamentary system is a complex whole that comprises of a set of connected parts. Frequently, parliamentary systems are defined in contrast to presidential systems and categorized by the distinctive institutional configurations that link the electorate, the legislature, and the executive. In a parliamentary system the electorate votes for representatives who, when assembled together, collectively constitute the representative institution of parliament. In turn, the political executive, or government, is then derived from the representative institution. Viewed as an ideal-typical process of delegation, a parliamentary system thus enables citizens to delegate decision-making capacity, through the medium of elections, to their representatives. In this process representatives, as the “agents” of electors, are authorized to act on behalf of citizens as “principals” (in the terminology of delegation theory). From this single direct act of delegation to representatives in parliament flows a sequential and serial process of delegation, whereby representatives in parliament then delegate the routines of decision making to a related institution—the political executive—which acts as the agent of the “principal” of parliament. In turn, the political executive (whether termed “cabinet” or “government” and normally headed by a chief executive known as a “prime minister”) delegates further to other “agents” in the institutional form of the bureaucracy or civil service. In contrast, in a presidential system, citizens elect and directly authorize both a political executive, either through elections or through an electoral college, and representatives in a legislature. In presidential systems, therefore, the electorate has two agents. Moreover, in presidential systems there is a separation of powers between the legislature and the executive, whereas in parliamentary systems there is a fundamental fusion of parliamentary and executive institutions.

LEGISLATIVE–EXECUTIVE RELATIONSHIPS

In a parliamentary system political executives are authorized by parliaments. This can take the form of a formal investiture vote before an executive takes office (Germany, Hungary, Greece, Ireland, Portugal, Spain, and Sweden) or immediately after an executive assumes office (Belgium, Italy, and Luxembourg). The outcomes of such votes are heavily dependent upon bargaining among political parties. In other parliamentary systems, executives are deemed to be authorized tacitly unless the executive loses the confidence of parliament (for example, in Australia, Austria, Denmark, Finland, France, Iceland, Japan, the Netherlands, New Zealand, Norway, and the United Kingdom). Using the concept “authorization” avoids using notions of the “selection” or “emergence” of executives from parliaments. In practice, few parliaments actively select leaders from their ranks, and in several states membership of the executive is incompatible with membership in parliament (for example, Austria, the Netherlands, Norway, and Sweden). Only in the UK and Ireland, among western European parliaments, are cabinet members required to be members of parliament.

In a parliamentary system executives are also accountable to parliament; in turn, parliaments are accountable to citizens. In the twenty-first century, ideas of parliamentary accountability are rooted predominantly in free competitive elections. In the strongest sense, executives are accountable to parliaments insofar as there are “no-confidence” procedures by which cabinets or governments can be collectively dismissed by parliament. In a weaker sense, executives may be held to account in terms of “informing” parliament and “explaining” their actions through oversight procedures such as questions, debates, and statements and by providing evidence to parliamentary committees. In an intermediate sense, executives may also be accountable where ministers are prompted by parliamentary scrutiny to accept culpability and to consider remedial action or redress.

The reciprocal relationship of accountability finds further reflection in the dissolution powers normally conferred upon prime ministers individually or cabinets collectively. In most countries the no-confidence procedures in parliament are counterbalanced by the executive’s capacity to invoke a confidence vote or to dissolve parliament directly. In all western European states since 1945 (as well as, for example, in Japan and Canada) executives have, on at least one occasion, dissolved parliaments before completion of the full electoral term. In Denmark, Greece, and Ireland some two-thirds of modern parliaments have been dissolved early. Upon dissolution, parliaments and political executives then face their ultimate accountability to the electorate.
PARLIAMENTARY SYSTEMS AND LEGITIMATION

As noted earlier, the terms parliament and legislature tend to be used synonymously and interchangeably. Yet few parliaments are legislatures in the literal sense of “lawmaker” (derived from the Latin words legis, meaning “law,” and ius, meaning “right,” or “propounder”). The formulation of legislative proposals in most parliamentary systems is conducted largely beyond parliaments, in executives operating in broader institutional networks of organized interests and political parties. In this case, the prime role of parliaments in the legislative process is the authorization of laws. Legislative outputs are legitimated through procedures of parliamentary deliberation, scrutiny, amendment, assent, and, ultimately, monitoring. Through processes of representation, the opinions and interests of wider civil society—variously in the form of individual constituents, territorial electoral districts or constituencies, political parties, or civil society associations—are brought to bear in the parliamentary processing of legislation. And, through these processes, popular authorization and legitimation of legislative outputs is secured. Indeed, in some systems, supreme legislative authority is deemed to reside in parliament (as in the concept of “parliamentary sovereignty” in the UK). In most parliamentary systems, however, the people are held to be “sovereign”—with authority delegated temporarily and contingently to representatives in parliament.

Much has been made in academic writings of a distinction between “deliberative assemblies”—with an emphasis on debate (linguistically the term parliament derives from the French verb parler, meaning “to talk”)— and “working assemblies”—with the emphasis on legislative functions. The former type of assembly is commonly associated with parliamentary systems and the latter with presidential systems. In practice, however, such distinctions are of restricted value. A more effective way of identifying and categorizing parliaments is encapsulated in the notions of “representation,” “authorization,” “accountability,” and “legitimation.” In linking citizens with their government, parliaments serve, in the first instance, to represent “the people” (however constituted in different countries) and also, indirectly, to authorize executive action. In the second instance, however, parliaments hold executives accountable for their actions and so provide an institutional mechanism for the public control, and ultimately, the legitimation, of government.

PARNES, HERBERT

1919–2006

Herbert Saul Parnes was a consummate social scientist, though his official title was professor of economics. Educated at the University of Pittsburgh (BA and MA) and Ohio State University (PhD), he spent most of his distinguished career as a labor and human resources economist at Ohio State, studying and teaching others about the experiences of people in American labor markets. His career also involved visiting professorships at Princeton and the University of Minnesota, a stint as an Organization for Economic Cooperation and Development (OECD) consultant in Paris, and three years at Rutgers following his retirement from Ohio State. Later, he returned to Ohio State as a National Institute on Aging grantee to continue his study of the labor market experiences of the elderly. His legacy as recounted below relates only to his substantive research, his pathbreaking contributions to the field of empirical labor market analysis, and his emphasis on a multidisciplinary focus. However, it must be noted that there are scores of economists and other social scientists to whom he was a teacher and mentor and whose own work bears witness to the significance of his scholarly contributions.

Parnes began his academic life as a political science major, and he never strayed from the idea that understanding human experiences in labor markets was valuable not only for its own sake but also for what it could contribute to the sensible formation of public policy. He was never a devotee of pure theory and recounts in his memoir, *A Prof’s Life* (2001), several instances when he undertook jobs and occupations to acquire a solid understanding of how workers really interacted with their jobs, coworkers, and employers. Although he acknowledged in the preface to *PEOPLEPower: Elements of Human Resource Policy* (1984) that his appreciation for the value of micro-economic theory grew during his career, he always believed that only the collection and analysis of data could

PARNES, HERBERT

1919–2006

Herbert Saul Parnes was a consummate social scientist, though his official title was professor of economics. Educated at the University of Pittsburgh (BA and MA) and Ohio State University (PhD), he spent most of his distinguished career as a labor and human resources economist at Ohio State, studying and teaching others about the experiences of people in American labor markets. His career also involved visiting professorships at Princeton and the University of Minnesota, a stint as an Organization for Economic Cooperation and Development (OECD) consultant in Paris, and three years at Rutgers following his retirement from Ohio State. Later, he returned to Ohio State as a National Institute on Aging grantee to continue his study of the labor market experiences of the elderly. His legacy as recounted below relates only to his substantive research, his pathbreaking contributions to the field of empirical labor market analysis, and his emphasis on a multidisciplinary focus. However, it must be noted that there are scores of economists and other social scientists to whom he was a teacher and mentor and whose own work bears witness to the significance of his scholarly contributions.

PARNES, HERBERT

1919–2006

Herbert Saul Parnes was a consummate social scientist, though his official title was professor of economics. Educated at the University of Pittsburgh (BA and MA) and Ohio State University (PhD), he spent most of his distinguished career as a labor and human resources economist at Ohio State, studying and teaching others about the experiences of people in American labor markets. His career also involved visiting professorships at Princeton and the University of Minnesota, a stint as an Organization for Economic Cooperation and Development (OECD) consultant in Paris, and three years at Rutgers following his retirement from Ohio State. Later, he returned to Ohio State as a National Institute on Aging grantee to continue his study of the labor market experiences of the elderly. His legacy as recounted below relates only to his substantive research, his pathbreaking contributions to the field of empirical labor market analysis, and his emphasis on a multidisciplinary focus. However, it must be noted that there are scores of economists and other social scientists to whom he was a teacher and mentor and whose own work bears witness to the significance of his scholarly contributions.

Parnes began his academic life as a political science major, and he never strayed from the idea that understanding human experiences in labor markets was valuable not only for its own sake but also for what it could contribute to the sensible formation of public policy. He was never a devotee of pure theory and recounts in his memoir, *A Prof’s Life* (2001), several instances when he undertook jobs and occupations to acquire a solid understanding of how workers really interacted with their jobs, coworkers, and employers. Although he acknowledged in the preface to *PEOPLEPower: Elements of Human Resource Policy* (1984) that his appreciation for the value of micro-economic theory grew during his career, he always believed that only the collection and analysis of data could
provide the understanding needed to undergird policy recommendations.

The signal accomplishment of his career was initiating and overseeing the single largest labor market research project ever funded by the U.S. Department of Labor, the National Longitudinal Surveys of Work Experience (NLS). It began in 1966 and has continued in modified forms into the twenty-first century. Literally thousands of scholarly articles, monographs, theses, and dissertations have been completed using what in the earliest years were known as the Parnes data. Parnes authored or coauthored more than fifty of those during his prolific career. Before that, he had published several significant works. In Research on Labor Mobility: An Appraisal of Research Findings in the United States, he synthesized everything known empirically to that point (1954) about worker mobility in American markets. He updated that synthesis a decade and half later in A Review of Industrial Relations Research (1970). His collaboration with other social scientists began early in exploring the economic, psychological, and sociological elements of a critical aspect of human decision-making in “Occupational Choice: A Conceptual Framework” (1956). This belief in the importance of multidisciplinary approaches carried over into the research team that he assembled at Ohio State’s Center for Human Resource Research to design and analyze the NLS data, which dismayed critics who believed it resulted in an underemphasis on economic theory.

Attesting to the policy importance of the NLS-based research are many studies of race and sex discrimination in labor markets, the salient factors related to the changing labor force participation of adult women, the impacts of schooling and training on the labor market success of various age-sex groups, and the correlates of changing retirement behavior among adult American men. Critical to the ability to offer policy recommendations on these and related issues is the longitudinal and detailed microeconomic character of the data that comprise the NLS. Furthermore, the collection of data on attitudes and a variety of schooling and training experiences enable testing of hypotheses about which only speculations were possible before the NLS existed. Among the attitude measures in which Parnes had profound scholarly interest were questions designed to tap into mobility as a propensity to move (by changing employers or occupations or geographic locations) as a predictor of later actual movement. This was, in part, born of his skepticism of the standard theoretical assumption that all workers are always seeking to improve their position in the marketplace and are always searching for information to enable such improvement. Though he coauthored several published studies using the data from these questions, many opportunities to exploit them exist for newer generations of social scientists, thus adding to Parnes’s contribution to our understanding how people really behave in labor markets and what social policies might be invoked to improve their well-being and the effectiveness of the economy in allocating and utilizing scarce human resources.

PARODY

Parodic practices carry implications for the study of social institutions and cultural frameworks because, especially when allied with satiric critique, they can lead to the clearing away of older modes of thought, and the opening up of alternate paradigms of cultural understanding. Not all forms of parody accomplish this skeptical questioning, emptying out, or overturning of an official perspective; normative parodies attack dissidents and divergences from the dominant cultural ideology and enforce established values. But parodies that reverse accepted hierarchies of value can serve as indicators of or even contributors to cultural change.

Parody—from the Greek para, “beside,” and odos, “song” or “derived from another poem”—involves both the repetition and inversion of some elements of an established work or genre, usually so as to lower what has been elevated or respected. Aristophanes, the first great parodist
in the tradition, implies conservative cultural allegiances in his comedies (written between 427 and 385 BCE), which parody the style and thought of Euripides, the last of the great Athenian tragedians, the philosopher Socrates, and the Sophists, the new, professional teachers of rhetoric.

The Satyricon of Petronius (early 60s CE) probably constitutes the best example from the ancient world of the use of satiric parody to empty out established canons of value. The longest surviving episode of this novel, “Trimalchio’s Feast,” satirizes the vulgar pretensions and mangled learning of the immensely rich former slave Trimalchio. But the dinner conversation of Trimalchio’s guests, who are obsessed with money, mortality, and the passing of the good old days, also parodies the dinner conversation of the aristocratic Athenians in Plato’s dialogue, the Symposium. Contrasting the honest vulgarity and materialism of Trimalchio and his guests with the corruption and hypocrisy of the educated narrator and his friends, Petronius achieves a portrayal of the lowborn, newly rich class that is neither caricatural nor condescending, and implicitly places them on a level with Plato’s high-minded Greeks.

In Gargantua and Pantagruel (first two books, 1532 and 1534), François Rabelais satirically parodies as illogical, ungainly, and repetitive the scholastic learning of the medieval universities that was authorized by the Catholic Church, and proposes by contrast the graceful, thoughtful, and persuasive eloquence of students trained in the new humanistic model of education. Where Rabelais criticizes a system buttressed by religious authority, Miguel de Cervantes, like Petronius, achieves in Don Quixote (Part 1, 1605; Part 2, 1615) a satiric critique of a previously dominant aristocratic culture, through parody of the romance epics of the Middle Ages and the Renaissance. Cervantes adopts the episodic structure of such works and their concerns with love and adventure; however, by making Don Quixote, the reader who believes in the literal truthfulness of these romances, repeatedly collide with contemporary social reality, he suggests the inadequacy of this narrative form in the more commercial world of his own time. He thus opens up a cultural space for the development of the new genre of the modern novel. In Gulliver’s Travels (1726), Jonathan Swift parody’s travelers’ tales in general and Daniel Defoe’s Robinson Crusoe (1719) in particular to satirize the arrogance of Englishmen and of Europeans in relation to the inhabitants of other parts of the world they were encountering through their voyages of discovery, commerce, and empire. In a similar way, Ubu Roi (1896), Alfred Jarry’s parody of the high genre of tragedy, and particularly of Shakespeare’s Macbeth, produces an acidic critique of middle-class intellectual and artistic culture that opened the way to such twentieth-century movements as dadaism and absurdist. Finally, to take a contemporary example, Thomas Pynchon’s novels from V. (1963) to Mason & Dixon (1997) consist almost entirely of parodic reworkings of established genres and discourses—from travel guides and spy novels to captivity narratives—to suggest a radical skepticism toward received understandings of history, technology, and power in the modern world.

Satiric parody has also affected cultures through popular media such as comics and television in the last half-century. MAD magazine made a mark in American culture during the 1950s and 1960s, puncturing pretensions by means of its irreverent parody of hit films and television shows. It was joined in doing so by a new form, the weekly satiric television news program, first with That Was The Week That Was (U.K., 1963; U.S., 1964–1965), then with “Weekend Update” (beginning in 1975 as a regular feature of Saturday Night Live). The latter lasted longer, but was more limited formally, consisting largely of comic anchors reading items based on stories in the news. The next most significant instances of parodic satire of politics and journalism in America consist of The Daily Show with Jon Stewart, followed by The Colbert Report with Stephen Colbert, which appear back-to-back four nights a week on Comedy Central. Stewart usually maintains a smile as he reports, often verbatim, the statements of newsmakers, spokesmen, journalists, and commentators; only occasionally does he let outrage show. By contrast, Colbert’s adoption of the persona of a hard-right cable talk-show host enables him to say what others find impossible to express: by zealously criticizing even the most well-grounded skepticism of government officials, their policies, and their bullying manipulation of mainstream media, he makes clear what the authorities believe but do not say, and allows the commonsense criticism to be expressed along the way.

In a famously controversial argument first published in 1984, Fredric Jameson maintained that in the postmodern period parody had become divorced from satiric critique. For Jameson, all that remained of parody was pastiche, a toothless, complacently unhistorical mixing of incongruous fragments from earlier styles. A year after Jameson’s essay, Linda Hutcheon by contrast argued that twentieth-century parodic forms do not possess a fixed and unfluctuating ideological persuasion: parody can be conservative or transgressive, or can even combine the two in an authorized transgression. Although, as Hutcheon and others have pointed out, the thought of Mikhail Bakhtin could be utopian in its emphasis on the possibilities for inversion and renewal through parody, most critics would agree that Bakhtin’s works (written from the 1930s through the 1960s) constitute the essential and seminal reflection on the renovating cultural work performed by satiric parody from the ancient world to the present.

PARSONS, TALCOTT
1902–1979
American sociologist Talcott Parsons, the youngest of five children, was born in Colorado Springs in 1902. His father was a Congregational minister, professor, and university president, and his mother was a progressive and a suffragist. Parsons completed his undergraduate studies in biology at Amherst College in Massachusetts. He also attended the London School of Economics, where he studied the theories of Max Weber (1864–1920). He translated Weber’s The Protestant Ethic and the Spirit of Capitalism (1904–1905) into English in 1930. Parsons was initially an instructor of economics at Harvard University, where he was mentored by Pitirim Sorokin (1889–1968), then became an inaugural member of the sociology department. In 1945 Parsons established Harvard’s Department of Psychology and Social Relations, an interdisciplinary collaboration in the behavioral sciences and economics. He served as chair of the department until its dissolution in 1972. He continued teaching as a visiting professor upon his retirement in 1973 from Harvard. Parsons died in May 1979.

Parsons was the major American social theorist until about 1969, and some claim that social theory since then has been in conversation with Parsons. Parsons attempted to develop a “grand theory” of society that explains all social behavior, everywhere, throughout history, and in all contexts, with a single model called structural functionalism. This approach considers values to be the core of culture, because values give meaning to what people do, direct people’s lives, and bind people together. These “cultural traits” thus function for the operation of society (Parsons 1966). Parsons believed that all lasting social systems strive for stability or equilibrium with a strong sense of social order and institutional interdependence. Influenced by Sigmund Freud (1856–1939), he was interested in how actors choose goals and means in relation to internalized norms and values, and argued for an objective external world that is understood empirically with concepts created by the ideas, beliefs, and actions of those under study. This is a modernist approach because it assumes an absolute developmental process.

Parson’s early theorizing on social action, influenced by Weber, focused on active, creative mental processes that have an important subjective component. In The Structure of Social Action (1937), Parsons developed his empirical approach of analysis based on observation, reasoning, and verification, and explored the difference between the concepts of behavior (a mechanical response to stimuli) and action (an inventive process and analysis of the subjective aspect of human activity) (Ritzer 2000). For Parsons, the basic unit of study is the unit act, which involves the following criteria: an actor/agent motivated to action; an end toward which action is oriented and means to reach this end; a situation where the action takes place; and norms and values that shape the choice of means to ends. Actions consist of the structures and processes from which humans are motivated to form meaningful intentions (through available goal-attaining means) that are put into practice within the social system (Parsons 1966). Parsonian “action” is considered from all of the following perspectives: culture (values), society (norms), personality (source of motivation), and organism (source of energy). For Parsons, people cannot choose goals and means without society in the background, and they cannot make sense of agency or action without enforced or expected social norms. This means people must have an intention and awareness of society’s norms, and they cannot escape these norms. Parsons is sometimes criticized for this position because he cannot account for social change.

Parsons was concerned with the integration of structure and process, and defined a social system as comprised of the interactions of many individuals within a situation, where the system itself includes commonly understood cultural norms. These cultural norms are within a system of generalized symbols and their associated meanings (Parsons 1951). These social systems have parts, or subsystems of varying complexity, that represent organizational structures. Additionally, social structures have social functions, which are the consequences of any social pattern for the operation of society as a whole. For Parsons, society is a complex system whose parts work together to promote solidarity and stability (they strive for equilibrium), and...
PARTIAL EQUILIBRIUM

With the publication of the first edition of his *Principles of Economics* in 1890, Alfred Marshall developed partial equilibrium analysis as a method for turning economic theory into a form that could be used to formulate policy and aid in the analysis of actual problems. He wanted economics to be “an engine for the discovery of concrete truth” (Hausman 1992, p. 152). In partial equilibrium each market or section of the economy is considered as a separate entity, and so its interdependence with other markets is not considered. This often is described as *ceteris paribus*, that is, other things do not change. To bring some order and understanding to an extremely complex world in which everything affects everything else, partial equilibrium concentrates on key relations, holding the rest constant (Hausman 1992). It is not that these factors are believed to be unchanging but that they are held in the *ceteris paribus* “pound.” As Marshall stated in 1922:

Ryan Ashley Caldwell

PARTIAL AUTOCORRELATION FUNCTION

SEE *Time Series Regression*.
The forces to be dealt with are however so numerous, that it is best to take a few at a time: and to work out a number of partial solutions.... Thus we begin by isolating the primary relations of supply, demand and price in regards to a particular commodity. We reduce to inaction all other forces by the phrase “other things being equal”: we do not suppose that they are inert, but for the time being we ignore their activity.... In the second stage more forces are released from the hypothetical slumber that had been imposed on them. (Marshall 1922, pp. xiv–xv)

Marshall suggested that, in each stage of the analysis, more factors could be allowed to vary.

The element of time is a chief cause of those difficulties in economic investigations which make it necessary for a man with limited powers to go step by step; breaking up a complex question, studying one bit at a time, and at last combining his partial solutions into a more or less complete solution of the whole riddle. In breaking it up, he segregates those disturbing causes, whose wanderings happen to be inconvenient, for the time in a pound called *Ceteris Paribus*. The study of some groups of tendencies is isolated by the assumption *other things being equal*.... With each step more things can be let out of the pound. (Marshall 1922, p. 366, emphasis in original)

**INTERDEPENDENCE IN PRICES AND MARKETS**

Marshall was fully aware of the interdependence between most markets and prices in the economy, as is apparent from notes XIV and XXI of the Mathematical Appendix to his *Principles*, where he outlined the basis of a general equilibrium system. However, he realized that attempting to analyze that interdependence would render the economic problem so complex that the main causal factors could not be isolated. Hence he regarded partial equilibrium analysis and the use of *ceteris paribus* as important approximations that allow casual inferences to be made and real-world problems to be studied.

In particular Marshall concentrated on the role of price in individual markets as the main determinant of the quantities supplied and demanded. To illustrate this, one can examine the demand for oranges (*D*<sub>0</sub>), which will depend on their price (*P*<sub>0</sub>), all other prices in the economy (*P*<sub>1</sub>, ..., *P*<sub>n</sub>), the income of all individuals in the economy (*Y*<sub>1</sub>, ..., *Y*<sub>m</sub>), the weather, people’s tastes, international factors, and so forth:

\[ D_0 = f(P_0, P_1, ..., P_n, Y_1, ..., Y_m, \text{weather, tastes, etc.}) \]

Some of these factors, such as weather and tastes, are not economic variables, and so they normally are considered exogenous. This does not mean that it is assumed that they do not change but that their changes cannot be explained within economics, and so they are unlikely to be influenced significantly by economic variables. What is left is the general equilibrium demand function for oranges in terms of all prices and incomes in the economy. Clearly this is extremely complex because in general equilibrium everything affects everything else. Therefore it is difficult to use the theory to make meaningful statements about policy or causality.

In partial equilibrium analysis each market is considered in isolation. When each market is concentrated on individually and when part of the economy is broken off and relations within that part are considered, causal inferences can be made. In addition it is assumed that demand and supply are separable and can be represented as independent curves, with price determined as the balance of those forces. To calculate the partial equilibrium demand function for oranges, the price of oranges is considered as the main determinant, other things being equal. In other words, all variables that are not determined within that market, particularly all other prices and incomes, are assumed for the analysis to be given and constant. This leaves the partial equilibrium demand curve for oranges:

\[ D_0 = f(P_0) \]

**MARSHALL’S FOUR TIME PERIODS**

According to Marshall, the question of which factors are left in the ceteris paribus pound depends on the time allowed for those factors to respond to changes in the market. In particular the length of time that is allowed for supply to respond to changed conditions will exert an important influence on the operation of the market. Accordingly Marshall distinguished four time periods that are appropriate for economic analysis, determined on the basis of which factors are held constant in each situation. The first is the very short run, or the market period in which it is assumed that goods are already at market and must be sold, so that supply cannot vary and price is determined mainly by demand. In the short period, quantity supplied is allowed to vary as a result of variations in production through changes in the variable factors, but the quantity and structure of fixed capital goods cannot be varied. As plants are fixed, firms can neither enter or exit the market, and so a supernormal profit can be made even in competitive industries. In the long period, plants can be varied, and firms can enter or exit from the market, and so all factors are variable. In this case no supernormal profit can be sustained in a competitive market. Finally, in what Marshall referred to as the “secular long period” knowledge, population, technology, and tastes all can vary.
APPLICATIONS AND PROBLEMS

Clearly, in evaluating partial equilibrium it is not relevant to consider the question of whether the underlying assumptions are realistic. As approximations, they are intended to focus on key relations, intentionally abstracting from secondary ones, which are held constant in the ceteris paribus pound. Demand and supply are determined by more than just the price of a commodity. However, in evaluating assumptions it is necessary to look at whether they capture the key aspects of any relationship, whether what is assumed away is as important as what is included, whether the variables that are assumed to be constant vary systematically with the variables included in the analysis, and whether the variables that are assumed to be independent, in this case supply and demand, are in fact interdependent.

As a result of these considerations, partial equilibrium can be applicable only to commodities that are relatively unimportant in terms of household budgets and that have neither close substitutes nor complements. If a commodity has close complements or substitutes, changes in its price will lead to changes in demand conditions in other markets, which will lead to changes in prices in those markets. This means that the variables that are being held constant will change as a result of changes in the endogenous variables. This contradicts the ceteris paribus clause because ceteris are not paribus. Any change in price will lead, through its effect on other markets, to a shift in the demand curves in the market that is being considered. The things that are being held constant vary systematically with the ones being looked at, and this undermines the basis of partial equilibrium. In addition if the commodity was an important part of the household budget, changes in its price would lead to changes in the household’s real income, thus changing another of the variables that have been held constant. In other words, for partial equilibrium it must be assumed that the income effect of a price change is very small. This means that the partial equilibrium framework is relevant only for goods on which only a relatively small proportion of the household budget is spent and for which there are no close substitutes or complements.

Further problems arise when the partial equilibrium framework is utilized to determine prices and outputs in competitive industries. A competitive industry will produce at that price for which aggregate demand for its output is equal to aggregate supply. In a partial equilibrium framework supply and demand must be independent of each other. The individual firm is assumed to face a U-shaped cost curve, and in perfect competition it faces an infinitely elastic demand curve. In long run equilibrium, price will cover costs exactly so that there are no economic profits.

In 1926 Piero Sraffa published an article that showed that there are severe logical problems in the use of the partial equilibrium framework for the analysis of perfectly competitive industries. He demonstrated that some elements of the analysis are inconsistent with partial equilibrium analysis and other elements are inconsistent with perfect competition.

Also, there are the standard problems associated with partial equilibrium analysis, specifically, the fact that demand and supply are often interdependent rather than independent and that the analysis is relevant only for unimportant markets. In other words, it is rare that one can break away part of the economy and assume that the interdependencies between it and the rest of the economy are negligible. Nevertheless, partial equilibrium analysis remains important in macroeconomics, particularly the distinctions between the short period, the long period, and the secular long period.

PARTICIPANT OBSERVATION

SEE Observation, Participant.

PARTICIPATION, POLITICAL

Sidney Verba and Norman Nie define political participation as, “those activities by private citizens that are more or less directly aimed at influencing the selection of government personnel and/or the actions they take” (1972, p.
2). This definition is broad in that it takes into account many activities beyond voting in elections, including being active in organizations, working on campaigns, contacting officials, attending political meetings, and being a member of a political organization (Verba and Nie 1972, p. 31). Other scholars adopt broader definitions. For example, Lester Milbrath (1965) incorporates passive behavior (i.e., taking part in ceremonial activities), some psychological orientations (i.e., becoming informed about politics), and protests and demonstrations. Scholars of nondemocratic systems include legal and nonlegal participation and mobilized participation, as well as activities more appropriate to these contexts, such as complaining through bureaucratic channels (Friedgut 1979; Huntington and Nelson 1976; Shi 1997).

Milbrath (1965) was the first to argue that political participation follows a hierarchical structure in that individuals who engage in activities at the top level also engage in activities at lower levels. The bottom rung includes those who do not engage in any type of activity. The “spectator” level consists of activities such as voting, exposure to political stimuli, and talking to others about politics. The “transitional” level includes attending meetings, donating money, or contacting an official. And the “gladiator” engages in activities such as running for office, soliciting funds, and working on a campaign.

Another way to look at the various types of participatory actions is with respect to the level of input required from citizens, the type of information the act conveys to leaders, and how much pressure they place on policymakers to pay attention (Verba and Nie 1972; Verba et al. 1995). Working on a campaign and directly contacting officials requires a great deal of initiative, while activities like voting do not entail as much time or energy. Direct contact sends a clear message to leaders about a citizen’s preferences, whereas voting only conveys an ambiguous message. Finally, activities vary with respect to the pressure they put on leaders, with voting exerting a high degree of pressure since electoral support is necessary for reelection.

WHO ENGAGES IN PARTICIPATORY ACTIVITIES

A prominent finding in the early literature, especially in the United States, was that socioeconomic factors, such as income and education, have the strongest effects on increasing the likelihood of turnout (Campbell et al. 1960). With respect to a broader range of participatory activities, those higher in socioeconomic status (SES) are also more likely to engage in the more difficult and time-consuming participatory activities (Milbrath 1965; Verba and Nie 1972), including nonconventional forms of participation such as demonstrations (Barnes et al. 1979).

However, Verba, Nie, and Jae-On Kim (1978) find that the relationship between SES and voting is not as strong across all countries, which they attribute to differences in institutions and social cleavages. Furthermore, in authoritarian regimes, individuals higher in SES are actually more likely to abstain from political participation, since abstention can be a form of protest (Shi 1997).

One of the problems with the SES explanation is that it does not explain why those lower in SES do participate in politics. Verba, Kay Schlozman, and Henry Brady (1995) propose mobilization as another factor that can help resolve the puzzle of why those low in SES may be inclined to participate. They argue (and find) that direct contact by political elites, such as direct mail or door-to-door canvassing, has a positive influence on the likelihood of turnout, and that this effect is more pronounced among those least likely to vote, since mobilization offsets the costs of participation. Rosenstone and Hansen also find positive effects of mobilization with respect to working on a campaign, donating money, and trying to persuade others to vote a certain way. Many scholars have subsequently demonstrated that direct contact increases the likelihood of turnout among minority groups (Leighley 2001) and is more effective than other types of mobilization, such as mailings and phone banks (Gerber and Green 2000).

IMPLICATIONS OF POLITICAL PARTICIPATION

Normatively, political participation has a long tradition of being considered important to the concepts of legitimacy and authority in democratic political systems. Whether one assumes an authorization view of representation, in which a leader is accountable to those who selected or appointed him or her, or an accountability view, in which the representative is bound to a free public, the standards...
for achieving both in a democracy are free and fair elections (Pitkin 1967). Thus, a political system is considered legitimate only given the participation of citizens in the voting booth. One problem with this conceptualization is that it tends to consider democracies as the only political system that provides legitimate representation (Rehfeld 2006). Participation is still relevant to the legitimacy of nondemocratic regimes, since citizen support is often necessary for the proper functioning of the system (e.g., Davis 1976; Friedgut 1979; Shi 1997).

Empirically, participation is important for the quality of representation in democratic systems: “democratic responsiveness depends on citizen participation, and equal responsiveness depends on equal participation” (Verba 1996, p. 2). Thus, inequality with respect to who participates can lead to biases in representation (Lijphart 1997). For example, scholars find that counties with higher turnout rates receive more appropriations from Congress (Martin 2003), and states with higher levels of upper-class representation have lower levels of welfare spending (Hill and Leighley 1992). Finally, Senator roll-call votes are responsive to the ideology of voters in a state, but not to nonvoters (Griffin and Newman 2005).

PARTICULARISM

Particularism is a philosophical position that, in brief, claims that reasoning can be rational and noncapricious without being structured using principles. (Noncapricious in this context means that we do not decide on a whim that a case is of a certain sort; there has to be consistency between it and other cases.) The opponents of particularists, generalists, deny this claim in various ways. Particularism has commonly been applied to reasoning concerned with what people should believe (epistemological reasoning) and how people should act (moral and prudential reasoning). It has attracted much attention, and the debate is carried out at a high level of abstraction. This has led to some splintering of the position; so much so that the definition given in this entry’s opening sentence is a controversial formulation. Jonathan Dancy has been the leading exponent of particularism.

Imagine that any element of a possible course of action—for example, that an action is a stabbing; that it
would be performed on a Tuesday—is a feature. Situations are collections of features. The debate raised by particularists concerns the nature of the contribution that features make to the value of the situations of which they are a part. Is it true that stabbings are always wrong, as crude generalists argue? According to particularism, sometimes stabbings are permissible, even obligatory, as in the case of self-defense. Even so, is it true that stabbings are always wrong-making, as more sophisticated generalists hold? That is, does the fact that an action is a stabbing always count against performing it, even though sometimes there are enough reasons to justify the action? Particularists deny that this has to be the case. By employing various arguments, distinctions, and examples, they argue that it is possible for the type of reason generated by a feature to change from situation to situation depending on the other features with which it is conjoined. Sometimes stabbings can be right-making. Particularists borrow a term from chemistry and claim that features can change their valency. (Some particularists make this claim about such features as justice, kindness, and the like.) If particularists are right, it means that there are no true moral principles apart from those with vague caveats such as “stabbing is often wrong-making.” (Particularists are trying to understand how such caveats work.) In other words, particularists think that reasoning can still be consistent, but this consistency is not captured by principles.

Particularism is not relativism. Particularists claim that the valencies of features can alter, while the reason generated by a feature on any occasion is an absolute, non-relative matter.

Particularism has important implications beyond abstract philosophy. If the particularist view is true, how does it affect our interpretation of the reasoning practices of judges in legal contexts? And should it alter how ethics are taught to various groups of people, such as those in the medical profession?

The new system succeeded in shifting the struggle for power away from the use of bullets toward the use of the newly devised electoral system. However, the system also produced a more authoritarian regime. Electoral fraud became characteristic of the one-party system from the beginning. For example, the 1929 election between PNR candidate Pascual Ortiz Rubio and opposition candidate and Mexican educator José Vasconcelos, who received support from the Christeros, or followers of Christ, was plagued with blatant acts of ballot-box stuffing and intimidation among other fraudulent activities that led to Ortiz’s victory (Castañeda 2000, p. xii). The Mexican novelist Carlos Fuentes described the stolen presidency as the result of “the first superfraud of the government party” (Fuentes 1996, p. 70).

By 1938 the PNR became known as the Partido de la Revolución Mexicana (PRM; Party of the Mexican Revolution) under President Lázaro Cárdenas, who ruled from 1934 to 1940. Cárdenas advanced upon Calles’s efforts to create a more peaceful transfer-of-power process by establishing the mechanism that allows Mexican presidents to choose their successors while also discouraging them from staying in power for longer than one six-year term. Naturally the party leader would choose a successor from within the party, which perpetuated the long cycle of one-party rule in Mexico’s political history.

This form of presidential succession became a point of controversy for the party. Although presidential elections took place in Mexico every six years, the process failed to fit the mold of a democratic political system. The journalist Philip Russell wrote, “The PRI maintains the fiction of democratic candidate selection” (Russell 1994, p. 76). Unlike the democratic system in the United States, for example, Mexico did not include primaries in which the public selected presidential candidates for each party prior to the national elections. Therefore the presidential succession mechanism allowed the incumbent president from the dominant party to wield more influence than the populace on the outcome of presidential elections.

Moreover the PRM underwent a structural transformation under Cárdenas known as corporatism. The new structural system was an alliance between the party and three other sectors—peasant, labor, and popular. Scholars have argued that this system of state-structured interest groups played a key role in determining political and economic results (Collier and Collier 1979). The three sectors functioned to keep the party in power by advancing the objectives of and voting for the party in return for special benefits for its members.

The influence of each corporatist branch under the leftist populist regime evolved over time. The peasant sector carried the most weight because of its large numbers. However, the sector’s clout declined as Mexico’s urban population surpassed that of the rural poor. The demographic shift enhanced the role of labor unions. As a result the party later relied upon the Mexican Federation of Workers to carry out its labor policies. Finally, the popular sector has been viewed as the most influential of the groups (Russell 1994, p. 79). The popular sector, which consisted of a broad range of groups from trade unions to slum organizations to professional organizations, had a large population and was organized under the National Confederation of Popular Organizations in 1943. Cárdenas envisioned that the three sectors would continue to carry out the revolutionary policies of the party and strengthen the alliance between them and the state. As a result the separation of powers in Mexico was more symbolic than actual.

State influence under the corporatist structure also spilled over into other areas of Mexican political life, thus threatening the democratic principles of checks and balances. The legislative and judicial branches as well as the media all followed the president rather than the rule of law and ethics most of the time (Castañeda 2000, pp. xii–xiii). The PRM dominated both the house and the senate because the president chose for congress PRM candidates who remained loyal to the party. The president along with the attorney general also selected judges who pledged allegiance to the presidential head of the party. The media outlets remained controlled and limited by the state until the late 1990s, even though newspapers and radio and television stations were mostly independently owned. The corporatist system became less effective as the country later moved away from a state-led government and economy toward a more liberal political and economic ideology.

Although the democratic nature of the Mexican political structure under Cárdenas remained questionable, Cárdenas also implemented successful social reform programs to ensure the equal treatment of all Mexican citizens. Fuentes described this period, stating, “And even if the upper and middle classes were favored, the working and peasant classes also received larger slices of the national pie than they ever had before or ever have had since” (Fuentes 1996, p. 71). Cárdenas carried out agrarian reform by returning to the Indian and peasant communities land that they had lost prior to the Mexican Revolution under the Spanish-controlled hacienda system. (Haciendas had been part of Mexico’s colonial economy since the sixteenth century. They were large pieces of land upon which the Spanish employed workers, predominantly of Indian origin. The Indian workers depended on the haciendas and were usually paid low wages.)

Cárdenas also promoted health, education, and other reform programs with the objective of alleviating poverty.
among Mexican citizens, including the Indian population, which often faced discrimination and suffered from inequality. The history of the PRI is not completely mired in corruption and failure.

Moreover in 1938 Cárdenas nationalized Mexico’s strongest export sector—oil—which contributed to the country’s economic success for a substantial period. The state control over Mexico’s petroleum protected the economy from the competitive forces of the global market for another four decades. Cárdenas’s approach contributed to 6 percent annual growth for the next forty years and increased salaries and purchasing power (Fuentes 1996, p. 71; Castaneda 2000, p. xv). Mexico was successful, relative to the rest of Latin America, at maintaining social peace and political stability. As a result the party under Cárdenas was characterized as promoting both social justice and economic growth while lacking in political democracy.

The party name changed to PRI and underwent another structural change under President Miguel Aleman Valdes in 1946. Alemán served as president from 1946 to 1952. Whereas the party under Cárdenas mostly emphasized social change, the new PRI’s dominant focus shifted toward economic development. By the mid-1950s until the late 1970s the Mexican state controlled the economy and instituted mechanisms to protect domestic producers from foreign competition. The goal of aligning social justice with economic development began to fade, and the gap between the wealthy and the poor continued to widen thereafter. The populist aspect of industrial development disappeared while the role of the state in the economy grew even more. The state’s alternative development goal included advancing the interests of private investors, both domestic and foreign (Walker 1995).

The departure from the measures put in place during the 1940s showed an even uglier side of the Mexican political system under the PRI. Social injustice and human rights abuses became even more overt by the late 1950s and continued well into the 1960s and 1970s. The alliance that civil society groups enjoyed with the state disintegrated. For example, workers’ movements were confronted, strikes were broken, labor leaders were incarcerated, civil society leaders were murdered, and student groups were attacked. Some cases include the murder of agrarian leader Rubén Jaramillo and the killing of students in the Tlatelolco Square massacre in 1968 right before the Mexico City Olympics.

Electoral fraud by the PRI did not continue only at the executive level. Rather, corruption plagued legislative elections as well. For instance, Félix Salgado Macedonio, opposition candidate for deputy in the second electoral district of the state of Guerrero and representative of the Frente Democrático Nacional (FDN; National Democratic Front), the antecedent of the PRD, exposed the fraud associated with the 1988 national elections before the congress. Macedonio presented the congress with a large number of ballots marked in his favor that authorities had partially or wholly burned, costing him an electoral victory over PRI candidate Filiberto Viguera (Fuentes 1996, p. 60). The congress eventually allowed Salgado to take his well-deserved seat while offering Viguera another congressional position.

THE DAWNING OF THE OPPOSITION POLITICAL PARTY

By the end of the twentieth century Mexico had experienced a profound change in its political system that demonstrated a move toward a more representative democracy. President Ernesto Zedillo of the PRI pushed for the first primary in Mexico starting with the 1999 elections. Zedillo’s break from political tradition, which kept the PRI in power at all levels of government, set the stage for other parties to have a fair opportunity and the people to have a real voice during national elections. As a result of these changes, a candidate from PAN was voted into the presidential office in fair, democratic elections. Many Mexicans compared the election to the fall of the Berlin Wall (Kaye 2000).

Vicente Fox Quesada, a former Coca-Cola business executive and former governor of the Mexican state of Guanajuato, won the Mexican presidency in 1999. He surpassed Francisco Labastida Ochoa, who was chosen to represent the PRI during the primary, with 43 percent of the vote to 37 percent. Cuahé Bec Cárdenas Solórzano, the candidate for the PRD and son of former Mexican president Cárdenas, followed with only 17 percent of the popular vote. Fox’s message of addressing the failures of the previous administration under Zedillo, such as resolving the conflict in the southern Mexican state of Chiapas and cracking down on drugs, resonated well with voters who had vivid memories of the problems under the PRI. For example, the 1990s were plagued with charges of corruption, political ties with powerful drug lords, the collapse of the Mexican peso, and an economic recession. PAN, in the words of the Mexican foreign minister Jorge Castañeda during an interview, served as the party “of prosperity, of modernization, of democracy, of respect for human rights” (Kaye 2000). The ideas of modernization and prosperity did not stray too far from the efforts of Mexican president Carlos Salinas de Gortari of the PRI during the early 1990s. Salinas pushed Mexico into a different direction economically by opening the country’s market and substantially reducing state involvement in the Mexican economy through the signing of the North American Free Trade Agreement (NAFTA) with the United States and Canada in 1994.
The PRI suffered an even more embarrassing defeat in the 2006 national elections. The PRI candidate Roberto Madrazo Pintado garnered only a little over 20 percent of the vote. However, the majority of the popular vote was split between two other opposing parties. The PAN candidate Felipe Calderón won the election by an extremely small margin relative to the PRD candidate Andrés Manuel Luis Obrador, with 36 percent and 35 percent respectively. Most analysts anticipated that Manuel Luis Obrador would win the election with his left-wing populist ideology, which emphasized social improvement, since early poll numbers showed him leading the national election. His campaign did not sound very different from the policies of Cárdenas fifty years before. It must be noted that Manuel Luis Obrador was a member of the PRI under the Mexican president Luis Echeverría’s administration from 1970 to 1976, but he left after being frustrated with the party’s inability to produce change (Castañeda 2006).

**FUTURE OF THE PRI**

Although the PRI lost the presidential elections in 1999, it continued to govern seventeen out of Mexico’s thirty-one states and dominated the congress. Under President Fox, the PRI still maintained a significant amount of authority in both houses of congress. The PRI was able to stall a number of Fox’s reform initiatives and even blocked one of Fox’s trips to the United States in 2002 (Peters 2002).

The PRI merely tried to remain afloat in Mexico’s political waters after badly losing its grip in both houses of congress in 2006. The party lost the majority of its seats in congress for the first time since its founding. PAN dominated both the executive and legislative branches of Mexican government as of 2007.

The future of the PRI remained bleak as the party suffered from internal turmoil. For the party to remain important in Mexican political life, it would have to redefine itself, emphasize coalition building, and establish a clear ideology and focus. In that the Mexican populace has become divided along the lines of left and right ideology, some analysts have even presented the possibility that the PRI, which is also divided along left and right ideological lines, may split into two separate political parties (Grillo 2006).

**PARTITION**

To paraphrase Winston Churchill, partition is the worst solution to political conflict, perhaps, except all others. Partition is an inadequate political tool whose time always comes when other solutions seem to be lacking. Often employed to resolve conflict and restore stability, partition frequently tends to exacerbate that which the division was intended ameliorate. In light of the tendency for partition to rise to the top of a list of options and the unintended
Partition is the political division of territory. It is usually employed to resolve violent ethnic or religious strife. By physically separating conflicting groups, those who advocate partition stress its conflict-resolution benefits and downplay its unforeseen costs. It is most often precipitated by armed conflict, which in several notable cases has invited some manifestation of international intervention. However, partition is not a panacea and often tends to increase rather than ease tensions.

Partition succeeds when the following occur: (1) both sides accept (albeit sometimes grudgingly) the division; (2) violent conflict has been permanently suspended; and (3) stability is restored, and a lasting peace can be guaranteed. All these factors considered, however, partition is often an inappropriate and unsuccessful method of conflict resolution. Indeed, partition may intensify differences, inflame ethnic rivalries, damage domestic infrastructure, and be accompanied by forced mass migrations. The desire to separate warring groups or factions to avert further violence may appear to be a rational response, but history has demonstrated that partition is an imperfect solution. Perhaps with the exception of the comparatively peaceful “Velvet Divorce,” in which the former Czechoslovakia was split into separate, homogenous, mutually consenting Czech and Slovak nations, one would be hard-pressed to locate an example of a truly successful partition (see Kumar 2003).

Partition fails when the following occur: (1) a partition agreement fails to meet the demands of opposing sides; (2) violence is not significantly diminished or eliminated (i.e., a permanent ceasefire has not been reached); 3) relations between opposing groups are not improved but rather deteriorate, culminating in renewed conflict. In this respect, partition has proven an ineffective political instrument. Conflicts are aggravated, rivalries are intensified, and in some instances violence continues uninterrupted. To explore why partition fails, consider its historical applications.

The partition of Palestine, while not only one of the most controversial territorial divisions in contemporary history, demonstrates the degenerative effect partition can have on ethnic violence. The eruption of violence between Jewish settlers and indigenous Arabs convinced the international community of the need to establish two independent states within the territory of Palestine: one Jewish and the other Arab. The partition was reluctantly accepted by the Jewish Agency but rejected by Arab leaders, who believed their right to national self-determination had been unjustly abrogated.

Following the 1948 war, Israel seized more land than had been provided under the United Nations Partition Plan, and as a result, hundreds of thousands of Palestinian refugees were displaced. The partition did little to mitigate the subsequent Arab-Israeli conflict; the division inflamed tensions, leading to several wars between Israel and its Arab neighbors. The occupation of Palestinian territory by the Israel Defense Forces followed the 1967 war. The occupation led to the emergence of Palestinian extremism, which in its various phases has waged a nearly interminable terrorism campaign against Israel. Although the partition of Palestine resulted in the establishment of an independent state of Israel, violence between Israel and Palestine, while abated by intermittent periods of calm, has continued almost without pause since partition.

Partition was not only the rage in Palestine; it was also the proposed British solution to the question of India. Two authors, Larry Collins and Dominique Lapierre, offer insightful examinations of both the partition of Palestine and partition of India in O Jerusalem (1988) and Freedom at Midnight (1997), respectively.

Like the partition of Palestine, the partition of India was both promising and problematic. To relieve itself of its colonial responsibilities in India, which had become increasingly onerous because of growing civil unrest and the high costs of maintaining a large colony, the British initiated the process of partitioning India into distinct, homogenous Hindu and Muslim nations. While the 1947 partition created independent Indian and Pakistani states, the division also resulted in a large-scale migration and widespread violence, displacing and killing multitudes of civilians.

The legacy of the partition of India has contributed to several long-term problems. These include myriad border disputes and the seemingly interminable conflict over the predominantly Muslim but Indian-controlled region of Kashmir. As of the end of the twentieth century, both states were in possession of nuclear weapons. This situation not only conjures up ever more nightmarish scenarios of Indo-Pakistani wars but has also served to attenuate stability on the subcontinent.

In other cases, partition was used by regional and global powers to create “spheres of influence” (Samaddar 2003). New states were suddenly being carved out and molded in the political and ideological image of more dominant states. Partition, therefore, is not only an instrument of conflict resolution but also a means of securing greater influence and political leverage in geopolitical regions of the world. On the Korean peninsula, the Soviet Union and the United States created proxies in North and South Korea. On Cyprus, an intense rivalry between Greece and Turkey split this tiny island into a modern Greek-supported state and a fledgling Turkish one, recognized only by the government in Ankara. And while armed conflict has not occurred in these areas for some
time, the prospect of another Korean War or Greco-Turkish conflict remains. The Demilitarized Zone between the two Koreas is the most heavily fortified border in the world, and Greece and Turkey continue to devote significant portions of their national budgets to defense expenditures.

Partition is also a potential solution to the ongoing conflict in Iraq, in which the country would be divided into separate Kurdish, Sunni, and Shiite governments. At the center of the discussion are commentators such as Leslie Gelb and Senator Joseph Biden (Delaware), who have proposed decentralizing Iraq into autonomous ethnically homogeneous Kurdish, Sunni, and Shiite federations. The plan assumes that fundamental ethnic differences, particularly between Iraqi Sunnis and Shiites, are what is fueling the insurgency and pushing Iraq perilously close to total civil war. Gelb and other proponents of this plan argue that by allowing each group to control its own affairs, sectarian conflict would diminish and U.S. forces would be allowed to withdraw and redeploy in smaller numbers to avoid a long-term American military commitment in Iraq.

But like most partition plans, the Iraqi partition plan is both promising and problematic. Partition may succeed in separating warring groups and reducing sectarian strife, but the creation of independent Kurdish, Sunni, and Shiite states presents a host of other problems. A Kurdish state is guaranteed to upset Turkey, which has been engaged in an ongoing struggle against Kurdish separatists; a Sunni state would likely be a source of further tension as very little oil is located in the area, which would be allocated to Iraq’s Sunnis; and finally, a Shiite state has the potential to become a radical theocracy aligned with Iran. Again, there are benefits to the solutions but there are also very dire and troublesome costs.

In the absence of more effective solutions, partition is often the only viable remedy remaining. Partition, though, is usually an insufficient method of conflict resolution because rather than reduce or eliminate conflict, it tends to exacerbate tensions. The purpose of conflict resolution, of which partition is a method, is to formulate a solution whose principal objective is to facilitate the cessation of further hostilities. Partition aims to resolve conflicts by separating opposing groups or factions that have demonstrated that they are incapable of coexisting within the same borders. But the employment of political division does not eliminate these problems as the architects of partition intend, but in many cases amplifies them.

PARTY SYSTEMS, COMPETITIVE

Competitive party systems can be defined in two ways. They may be defined as all party systems in democratic countries, where competition among parties is at least theoretically possible. Alternatively, they may include only those party systems in which elections involving actual competition among two or more parties routinely takes place. For the sake of a broader focus of competitive party systems, the alternative definition is more encompassing and defined further in this entry. Competitive party systems differ from one-party systems primarily in terms of the number of parties that are able to seriously compete for power during elections. In one-party systems, a single dominant party routinely wins elections by a wide margin while all other parties receive quite small vote shares. In competitive party systems, by contrast, two or more parties generally receive substantial numbers of votes during elections. Hence, there is the possibility of alternation in power, in which the party that governs the country at the point of the election loses to an opposition party.

Because one or more opposition parties can meaningfully threaten the governing party with removal from power, elections in competitive party systems can serve as contests among various visions for the future of the country. Anthony Downs, in An Economic Theory of Democracy (1957), showed that, under certain conditions, the competitive nature of elections causes party systems to become extremely responsive to the ideological and policy desires of the electorate. If elections are decided primarily on the
basis of parties’ alternative platforms and proposals, then, competitive party systems may outperform one-party systems in terms of representation.

Elections in one-party systems are often thought to be characterized by patronage politics; that is, gifts of goods or services from the political party to voters. However, patronage politics play an important role in competitive party systems, as well; parties may use patronage to win voters who prefer another party’s ideology or policy proposals. At the extreme, elections can become a contest to see which party can offer more patronage to a larger number of voters, with ideology and policy issues entirely neglected. Hence, patronage threatens to undermine the advantage that competitive party systems have over one-party systems in terms of representation.

The majority of party systems in democratic countries throughout the world are competitive rather than one-party systems. Democratic one-party systems have proven viable for long periods of time in several countries, such as Japan, Botswana, and Sweden. In other countries, such as Mexico and Singapore, maintenance of a one-party system depended on the ability of the government to impose restrictions on democracy. However, most party systems in democratic Europe and in the Western Hemisphere have been competitive, as have the party systems of some democratic countries in other regions.

KINDS OF COMPETITIVE PARTY SYSTEMS

The most common approach to differentiating among kinds of competitive party systems is to distinguish by the number of parties that have a meaningful chance of winning elections. By definition, competitive party systems contain at least two important parties, but they sometimes have many more. Hence, the simplest distinction to make is between two-party and multi-party systems. Giovanni Sartori’s *Parties and Party Systems* (1976) extends this typology, dividing multiparty systems into limited pluralist systems with three to five important parties and extreme pluralist systems with more than five significant parties. Two-party and limited-pluralist systems lead political parties to moderate their ideologies and policy proposals in order to win the support of centrist voters during elections. Extreme pluralist systems, by contrast, are said to encourage parties to radicalize their proposals in order to differentiate themselves from the many competitors within the party system.

Since the publication of Sartori’s work, discussion has focused on a quantitative classification of the number of effective parties in a competitive party system, typically denoted as N. Because N is a continuous measure of the number of meaningful parties in a system, it allows precise descriptions of differences in party systems across countries and over time. If S_i represents the vote share of the ith party in a given election, the formula for N in that election is:

\[ N = \frac{1}{\sum S_i^2} \]

Other analysts have proposed that competitive party systems be distinguished according to their degree of institutionalization. A highly institutionalized party system is one in which the same set of specific political parties persists across elections, the parties have well-developed organizational and psychological connections to the electorate, and party leadership succession is handled by well-specified intra-party procedures. By contrast, a weakly institutionalized party system consists of parties that appear and disappear as organizations on a relatively regular basis; parties form only weak, temporary ties with voters; and party leadership is intensively concentrated in specific individuals, creating a major party crisis each time that a new leader is needed. Most party systems in developed countries are relatively institutionalized, whereas many party systems in less-developed countries and in the post-Soviet world are more weakly institutionalized.

CAUSES OF DIFFERENCES IN PARTY SYSTEMS

What factors determine the kind of competitive party system that a democratic country will have? Scholars have offered two major explanations of observed divergences in the number of parties within a party system: the number of major divisions within society, and electoral rules.

In their essay “Cleavage Structures, Party Systems, and Voter Alignments: An Introduction” (1967), Seymour Martin Lipset and Stein Rokkan argued that European party systems have been profoundly shaped by the resolution that each society has found to a series of shared challenges, each of which encourages a new segment of voters to form a lasting attachment to some specific political party. For example, if the society resolves debates over the proper relationship between church and state early on by allowing religious liberty, then the party system is likely to lack political parties based on divides among religious denominations. If, however, state sponsorship of one particular church persists, then political parties may be expected to form along religious divisions in order to either contest or protect the established church’s privileges. A major implication of this idea is that societies with a larger number of major social divisions will have more political parties than societies that are divided along fewer important social lines.

Maurice Duverger’s *Political Parties, Their Organization and Activity in the Modern State* (1954) explains...
differences in the number of political parties within a competitive party system in terms of electoral rules. He argues that electoral systems in which only one candidate per electoral district can win produce two-party systems. On the other hand, electoral systems that allow multiple winners per district result in multi-party systems. Hence, decisions about electoral rules are one of the major tools that societies have for managing the kind of competition that emerges among parties within a party system.

To date, no meaningful consensus has emerged about the factors that cause party systems to become institutionalized. Scholars have argued that greater length of democratic experience and higher levels of economic prosperity may encourage the institutionalization of competitive party systems, but these arguments are understood to be at best partial explanations of the phenomenon of institutionalization among competitive party systems.

PASINETTI, LUIGI
1930–
Luigi Lodovico Pasinetti was born in Zanica, Italy (near Bergamo), on September 12, 1930. Since 1962 he has been a professor of economic analysis at the Catholic University of Milan, where he had obtained his degree in economics in 1954 under the tutelage of Francesco Vito (1902–1968) and Siro Lombardini (b. 1920). Pasinetti moved to Cambridge University in 1956. He completed his PhD there in 1962 and later became a reader in economics. Study at Cambridge, with research visits at Oxford, Cambridge (Massachusetts), and elsewhere, allowed him to gain access to the top economic journals. His early paper on Ricardian economics (Pasinetti 1960; Pasinetti 1974) remains a classic.

Pasinetti’s own research is, first and foremost, an inquiry into the dynamic theory of economic growth and income distribution. His doctoral dissertation, “A Multi-Sector Model of Economic Growth,” developed into a well-known piece of analysis (Pasinetti 1965), which would further develop into his 1981 book Structural Change and Economic Growth (see also Pasinetti 1993). His entire body of work, in a characteristic Cambridge fashion, is explicitly rooted in classical economic analysis. Pasinetti, who has always felt a deep attachment to Cambridge, became the senior heir of the Cambridge post-Keynesian school (Pasinetti 2006). He was closely associated, in particular, with Richard Kahn (1905–1989), Nicholas Kaldor (1908–1986), Joan Robinson (1903–1983), and Piero Sraffa (1898–1983). From 1976 onward, Pasinetti turned full-time to his Milan Chair at the Catholic University, where he was elected dean of the faculty of economics. A dedicated teacher, he is also the author of a well-known textbook on the theory of production (Pasinetti 1977).

During the 1960s Pasinetti’s theoretical hits were outstanding and surprising. His 1962 theorem (also in Pasinetti 1974) on the Cambridge equation would soon become famous and give rise to a vast literature. This equation is a long-run equilibrium relationship between the rate of profit and the rate of growth, usually given as \( r = n \), where \( r \) is the rate of profit, \( n \) is the rate of growth of the population, and \( s \) is the rate of savings of capitalists. Pasinetti’s contribution demonstrated that, surprisingly, the workers’ rate of savings has no effect whatsoever on the equilibrium rate of profit. Pasinetti’s creative insight thus provided a correction and an intriguing generalization of the Kaldor model of growth and distribution. This theorem has also been called the Pasinetti paradox. Thereafter, it became customary to speak of the Kaldor-Pasinetti model of growth and distribution. Mauro Baranzini and G. C. Harcourt (1993, pp. 12–17) discuss in detail the various strands of analysis to which the Pasinetti paradox has given rise.

Pasinetti was an important participant in the Cambridge capital controversies. In 1965 David Levhari, a student of Paul Samuelson, published a paper that sought to demonstrate that some of the paradoxes in capital theory that had emerged in the literature and had been brought into full light in 1960 by Sraffa only had limited validity. However, Pasinetti proved conclusively that there were no grounds for such an attack on Sraffa and the Cambridge view. Pasinetti’s paper was first presented in 1965 in Rome at the First World Congress of the Econometric Society. The following year it opened a special issue of the Quarterly Journal of Economics (Pasinetti
Pasinetti Paradox

1966), where Levhari's theorem was acknowledged to be false by the author and by Samuelson himself. It was an impressive showdown that honors the economic profession and has since given rise to a full range of insights in the theory of capital (Pasinetti 1969).

Pasinetti’s scientific contributions focus on two main issues: (1) the critique of the neoclassical system; and (2) the completion of the Keynesian system and its extension to distribution and growth. Pasinetti’s most significant contribution on both accounts is found in Structural Change and Economic Growth (1981), one of the outstanding achievements in economic dynamics. Along with his dissatisfaction with aggregate dynamic models and the deceiving character of a number of disaggregated models (e.g., John von Neumann's model), it is the historical fact of the widespread unevenness of development processes—Pasinetti himself argues—that provides the drift to structural dynamics.

Pasinetti’s contribution to economic growth theory has a special place: His system provides the only theory focusing on the conditions under which an economic system will reach and maintain full employment and full capacity utilization in the long run when the system is subject to structural change. Classical economic analysis, here again, provides the foundation to his framework. But Pasinetti has no interest in establishing a canon or dogma on value and distribution: Rather, by building on the open and innovative side of the classical tradition, his schemes of structural economic dynamics focus on technical progress and human learning and form a pathbreaking contribution to growth theory.

BIBLIOGRAPHY

**PASINETTI PARADOX**

The Pasinetti Paradox arises in a model of an idealized economy inhabited by two distinct classes: workers who save a fraction of their wages and of any profit income (also called interest) earned by their past savings; and capitalists who live exclusively off the profits generated by their wealth, saving a fraction, \( s \), of their profit income. All wealth is held in the form of capital, and the ratio of profit to capital is called the rate of profit (or the rate of interest by some writers), \( \rho \). The growth rate of capital is equal to the growth rate of the labor force, \( n \), so that the economy remains in a state of full employment. Under these conditions, Luigi L. Pasinetti showed that a very simple equation describes the long-run (or steady state) relationship between the rate of profit and the rate of growth: \( \rho = n s \). This remarkable equation implies that the rate of profit is determined by the rate of growth and the saving rate of the capitalists, independently of the saving of workers or the underlying technology of the economy, which constitutes the Pasinetti Paradox. It has been at the center of a lively controversy between two different schools of economic thought since its discovery.

One might find it paradoxical that an increase in the saving rate of workers would have no effect on the rate of profit since this, by making capital (e.g., machines and factories) more abundant in relation to labor, might bid...

Pier Luigi Porta
up wages and drive down the rate of profit. Pasinetti (a leading classical or neo-Ricardian economist) showed that this effect will not persist into the long run. The rate of profit will decline temporarily, but that would reduce the income of capitalists, allowing the share of wealth owned by workers to increase. Because workers are, by assumption, less thrifty than capitalists, this redistribution will eliminate the need for any change in the rate of profit in the long run. Profits thus have a privileged status in the classical theory of income distribution, for capitalists receive a rate of profit that is just high enough, after deductions for their own consumption, to support the saving necessary for sustained full employment; wages emerge as a kind of residual.

The neoclassical economists find it paradoxical that the rate of profit is not in some way determined by technology, as this seems to refute their marginal productivity theory of income distribution. Paul Samuelson and Franco Modigliani (leading neoclassical economists) pointed out that the Paradox only applies to an economy in which the workers’ saving rate is low relative to the capitalists’ saving rate. When workers save so much that their wealth grows permanently faster than the capitalists’ wealth, the system will tend toward a one-class economy in which the capitalists’ share of wealth becomes vanishingly small. This discovery led to an ongoing controversy about whether the two-class or one-class model better describes existing capitalist economies. While the early debates were often tied up with the validity of the marginal productivity theory, it has become evident that even when marginal productivity theory fails, it is usually possible for an economic model to have two possible outcomes, depending on whether the workers’ saving propensity exceeds or falls short of some well-defined threshold value.

PASSING
Passing refers to a person changing his or her racial or ethnic identity. The term entered the common vocabulary under Jim Crow—the regime of racial segregation in the United States that emerged in the late nineteenth century and lasted into the 1960s. During this time period, many U.S. states and communities adopted the “one drop rule,” which held that a person with any African ancestry whatsoever—no matter how remote—would be classified as “Negro.” Under Jim Crow, many people with “one drop of black blood” chose to identify as white to evade racial discrimination. Numerous novels and films of this period portrayed the phenomenon, usually in the form of a tragedy.

Two types of individual passing occurred under Jim Crow. In “situational passing,” a person of color presented a white identity only in certain situations—for example, to obtain employment in a white-only workplace or to gain entry into a white-only public facility such as a theater or train car. The situational passer retained his or her minority identity at home. The temptation of situational passing was generally understood and tolerated among the African American population.

Some people engaged in full-time passing, commonly referred to as “crossing over” or “passing over.” A person who permanently crossed over the color line into a white identity cut most social ties with African American family members and friends. Avoiding contact with other blacks was necessary to prevent arousing suspicions within a new, white social milieu. Because people who crossed over were lost to the African American community, this type of passing was widely condemned by black editorialists and political activists.

In the United States, the Jim Crow–era conception of “passing” implied some degree of subterfuge, in which the person who passed was seen as an impostor who deceived his unsuspecting audience. This conception of passing emerged in the historical context of scientific racism and the one-drop rule, which made the color line seem a rigid boundary based on science rather than a social construction.

In other times and places, changing racial-ethnic identity was commonly done out in the open, often in the court system or as part of a public appeal. Caribbean and Latin American countries did not develop the rigid, one-drop conception of nonwhiteness that existed in the United States under Jim Crow. The saying “money whitens” is a bit of folk wisdom that observes the conflation of class with race, that a rich man is more likely to be accepted as an honorary white than a poor man. In the Spanish colonies, it was possible to purchase through the court system a cédula de gracias al sacar—an expensive document that was valuable because it officially removed
legal disabilities from the document’s bearer, such as illegitimate or multiracial birth status.

Such “passing by permission” was possible in situations where the color line was less clearly defined and thus more permeable. Passing by permission was occasionally available in the United States prior to the Jim Crow era. Some courts granted status as an honorary white to individuals of sufficiently light complexion and sufficiently respectable social status. However, this type of passing became rare in the post–Civil War era. By the early twentieth century, as the one-drop rule gained sway, passing by permission was mostly defunct in the United States.

Although individuals could not pass by permission in the United States under Jim Crow, “group passing by permission” did occur. In rural areas of the southern Atlantic seaboard, communities of mixed ancestry who had been free before the Civil War were occasionally permitted to convert to an American Indian identity and given a slightly higher status than freed slaves (Berry 1963). The motivation for the white community was to pretend that racial mixing between whites and slaves had never occurred by re categorizing the offspring of such unions as Indians. Another motive for conservative white politicians prior to black disfranchisement was that they were able to co-opt lighter-complexioned voters by making them honorary Indians, thereby gaining support for Jim Crow from a portion of the nonwhite population.

As the Jim Crow era ended in the 1960s, racial-ethnic identities became seen more as an option that each individual could choose for himself or herself (Waters 1990). For people of mixed ancestry, self-identification became an acceptable standard, replacing the rigid one-drop system to some extent. As a consequence, reports of African Americans passing as white have mostly disappeared today.

By the late twentieth century, a new phenomenon had emerged—“reverse passing”—in which people raised with a white identity would claim a minority identity to benefit from minority set-asides in business, education, or government. For example, a federal court determined that the Malone brothers of Boston had falsely claimed to be African American to gain employment in the city’s fire department under affirmative action criteria (Ford 1994).

More common is the phenomenon of the white “wannabe” passing as American Indian. In one notable case, a former white segregationist politician named Asa Carter adopted a new identity as Forrest Carter and achieved best-seller status as a Cherokee author. In the academy, Ward Churchill was exposed as having falsely claimed to be enrolled in the Keetowah Cherokee Nation in order to advance his career as an ethnic studies professor at the University of Colorado. Genealogical research revealed no evidence of Churchill’s claimed American Indian ancestry. After complaints by a group of American Indian professors in the early 1990s, some universities now require that applicants must show proof of tribal enrollment when requesting affirmative action review as American Indians. However, racial-ethnic self-identification remains the de facto standard in most workplaces today, which makes passing mostly a thing of the past.

**PASSION**

**SEE** Eroticism.

**PASSIVE RESISTANCE**

Passive resistance commonly refers to actions of nonviolent protest or resistance to authority. The central feature is the conscious choice by the actors to abstain from a violent response even in the face of violent aggression. The term came into common use during the independence struggle in India between the 1920s and 1948. It has been used widely by groups who lack formal authority or position and has sometimes been called the “weapon of the weak.”

The term is misleading, however, in that it implies passivity. In fact, passive resistance can be thought of as an active, but nonviolent, mode of struggle in a social conflict. The actions that fall under the term passive resistance include many forms of civil disobedience and noncooperation—such as sit-ins, boycotts, blockades and occupations of buildings, tax refusal, and alternative publications.
and media. More active forms of passive resistance include strikes, walkouts, protest marches, theatrical protests, and hunger strikes.

Passive resistance is rooted in a relational view of political power that sees the rulers of a community or nation as dependent on at least the acquiescence of those who are ruled. Thus, even a dictator’s power rests to an important extent on some level of cooperation by the population. This view was articulated by Étienne de la Boétie (1530–1563) in the sixteenth century, as well as by John Locke (1632–1704). The premise that governance derives its legitimate authority only from the consent of the governed is the foundational idea of modern democracy.

One of the foremost contemporary scholars of the political perspective of passive resistance is Gene Sharp. Sharp argues that nonviolent struggle may reflect a moral commitment to pacifism by leaders or activists in a movement (Mohandas Gandhi [1869–1948] and Martin Luther King Jr. [1929–1968] are prominent examples), but pacifism is not a necessary condition. Passive resistance can be explicitly calculating, practical, and strategic and used effectively by those with no moral commitment to pacifism. In the long view of history, it is likely that very few practitioners of passive resistance have been moral pacifists. Arguably, the social power wielded through passive resistance also is democratizing, because it disperses power broadly in society. Like moral pacifism, however, nonviolent struggle does not depend on democracy to be used.

Seen in this broad scope, passive resistance has a long and varied history. Techniques of passive resistance are evident in Aristophanes’ play Lysistrata (411 BCE), where the women refuse to have sexual relations with their husbands until the men cease their war making. During the War of Independence (1775–1783) in the United States, colonists refused to obey British demands for stamp taxes or for the billeting of troops. Henry David Thoreau (1817–1862) famously articulated his call for civil disobedience with his act of tax refusal during the Mexican War in the 1840s. Suffragists held demonstrations in major cities in the United States and Great Britain in the early years of the twentieth century; a few participated in hunger strikes.

Examples of passive resistance are easily found in many societies in the late twentieth and early twenty-first centuries. Student protestors occupied Tiananmen Square in Beijing in 1989. Nonviolent movements across Eastern Europe brought down Communist governments in the same year. In 2000 a nonviolent movement in Serbia ended the dictatorship of Slobodan Milošević (1941–2006). Civilians on both sides of the Israeli-Palestinian conflict have periodically employed the technique. Indigenous peoples forced the collapse of the government in Bolivia in 2005 with protests and work stoppages.

The most important development of the concepts of passive resistance came from Mohandas Gandhi and the Indian campaigns for independence. As a young lawyer in South Africa at the turn of the twentieth century, Gandhi organized Indians to resist discrimination and unequal treatment. Claiming their rights as citizens of the British Empire, they refused to carry passes and held public acts where they burned the government-issued passes. Out of these experiences, Gandhi developed his idea of satyagraha, which is often translated as “soul force” or “truth force.”

One of the key principles of Gandhi’s use of passive resistance was to find opportunities to publicly confront unjust laws or authority. Protestors, or satyagrahis, defied the laws, but sought to maintain a posture that treated the agents of authority with respect and even compassion. Gandhi argued that the means of struggle must be morally compatible with the ends being sought. Protestors often submitted to arrest and even violence, but did not resort to violence themselves. In a protest march to the gates of the saltworks in Dharsana in 1931, for example, protestors willingly walked up to the waiting police, who beat them brutally.

Passive resistance gained a broad public recognition in the United States as the civil rights movement exploded in the 1950s and 1960s. Throughout the movement years, techniques of passive resistance were used both to assert a moral position about rights and equality and to apply economic and political pressure. Martin Luther King Jr. drew on Gandhi and his own Christian tradition to formulate a strategy of nonviolence. Like Gandhi’s satyagrahis, civil rights activists marched peacefully and publicly in Birmingham, Alabama, in Selma, Alabama, and elsewhere. They also accepted upon themselves the costs of their actions, including discomfort, arrest, beatings, and even death.

Nonviolent actions often also exerted economic and political leverage. Boycotts of busses and department stores pressured private business to end their policies of exclusion. Sit-ins at segregated lunch counters disrupted business until owners relented. Defiant demonstrations often led to mass arrests, which encumbered the police and judicial systems. Provocations of the police to brutality gained national and international political sympathy for the movement.

In the late twentieth and early twenty-first centuries, the uses of passive resistance in many conflicts around the world became more overtly strategic and less concerned with the moral character of the tools. Passive resistance, one of many forms of nonviolent action, provides a source of power to those disenfranchised from traditional poli-
tics. When used as part of broader strategy, it has contributed to powerful movements for social change.

PATH ANALYSIS
Path analysis is a widely used technique for modeling plausible sets of causal relations among three or more observed variables. In the social sciences path analysis has been widely used especially in sociology, and also in psychology (most notably in areas of child or lifespan development or other longitudinal research); elsewhere, it has proven useful in biology, particularly in genetics (including behavioral genetics).

PATH DIAGRAMS
Path models are typically represented in the form of path diagrams, but can also be modeled as a set of regression equations. A path model can include any number of independent (or exogenous) variables, any number of dependent (endogenous) variables, and any number of intermediate variables, which are both dependent on some variables and predictive of others. In a path diagram, each variable is represented. The hypothesized links among variables are shown by arrows, representing predictive or correlational relations.

In most cases all of the exogenous variables are modeled with all possible correlations among them represented. A failure to include such a correlation would in effect be a hypothesis that that correlation equals zero, which is rarely applicable to measured variables. Endogenous variables (those with predictive arrows, or paths, leading to them) cannot be included in correlational relations. Typically each endogenous variable will have one additional path leading to it from an unspecified source, representing all sources of variance in the endogenous variable that are not already modeled, called the residual or the disturbance. The absence of this arrow indicates a hypothesis that all of the variance is accounted for in the model which, again, is rarely the case. These residual variance sources are unmeasured exogenous variables that can be correlated with each other or with observed exogenous variables.

MODEL ESTIMATION
When the path model has been established, the next step is to estimate the path coefficients. In conventional multiple linear regression, two or more independent (or exogenous) variables are modeled as predicting one dependent (endogenous) variable. The coefficients derived in multiple regression are partial regression coefficients: the regression of the dependent variable on each independent variable, holding the other independent variables constant. Path analysis is much the same. Each path coefficient is a partial regression coefficient: again, the regression of the specified endogenous variable on the specified “upstream” variable, controlling for the other variables that have paths leading to the endogenous variable. And thus the path coefficients are interpretable as partial regression coefficients: the change in the downstream variable per unit change in the upstream variable, holding all other variables constant. Certain hypotheses involving the path coefficients can be tested as in regression, such as the null hypothesis that the path coefficient equals zero, which is tested by the ratio of the coefficient to its standard error. In fact, if the path model is a recursive system, such that the predictions of downstream variables from upstream can be depicted in a block triangular matrix (where the matrix elements are the effects of the upstream variables [columns] on the downstream variables [rows]—i.e., no variable is both upstream and downstream of a given other variable), then the path analysis can be completely conducted as a series of sequential ordinary least squares regression analyses. In more complex models, other algorithms such as maximum likelihood are needed.

More commonly the path model is estimated in software for structural equation modeling. Structural equation modeling is an extension of path analysis, in which the paths of interest are typically among latent (unmeasured) variables, or factors, with an explicit measurement model linking the factors to observed variables. As a special case of structural equation models, path models can easily be fit in the more sophisticated software.

An important benefit of such software is that it calculates a number of indices of fit of the model. A fitted path model allows for the calculation, from the various path
coefficients and estimated variances, covariances, and residual covariances, of a model-implied variance/covariance matrix of the original variables—that is, a covariance matrix that is consistent with the fitted model. Broadly speaking, the fit of the model is an assessment of how well the model, with its estimated coefficients, implies a covariance matrix that matches the original matrix from the data. If there is no significant discrepancy, as measured by a chi-squared statistic, then it may be concluded that the path model is consistent with the data. Note that this does not necessarily indicate that the model is an accurate depiction of causation in reality, but only that it is not inconsistent with reality as indicated by the covariance matrix.

There has been, however, much debate over the utility of the chi-squared statistic. It is widely agreed that a non-significant chi-squared results in a failure to reject the model. However, there may be cases where the chi-squared statistic is sensitive to small deviations between the actual and implied covariance matrices that are not of practical importance to the researcher; this is especially true when the sample size is large. As a result, numerous statistics have been developed to assess approximate or close fit. Among the more prominent of these are the Comparative Fit Index, the Tucker-Lewis Index, and the Root Mean Squared Error of Approximation.

**HYPOTHESIS TESTING**

The test of model fit is one of the primary results of fitting a path model. Other hypotheses of interest in path analysis frequently involve constraints on the path coefficients: for example, that two path coefficients are equal to each other, or that a set of three coefficients are all equal to zero. These can readily be tested in structural equation modeling software by the estimation of nested models. In this situation the fit of a full model (without the constraints) is compared with a restricted model (with the constraints applied in the estimation process). Two such models are nested if the restricted model can be created strictly by imposing constraints on the full model. If the full model fits the data well, then the difference between the chi-squared statistics for the two models is itself distributed as a chi-squared, with degrees of freedom equal to the number of constraints applied. A significant chi-squared statistic indicates that the restricted model fits significantly less well than the full model.

**APPLICATIONS**

Path analysis has found utility in a number of areas of the social sciences. Two areas in which it is most prominently featured are behavioral genetics and longitudinal research. In behavioral genetics, one of the most common tools for evaluating heritability is the ACE model, a path model which allows partitioning of variability in twin studies into additive genetic effects, common (shared) environmental effects, and non-shared environmental effects. In child development or lifespan development—or any longitudinal study—path analysis is well suited as the causal direction between variables is typically unambiguous: The hypothesized causation is from the temporally prior variable. Finally, path analysis can be especially useful in intervention studies to identify mechanisms that may mediate the effects of the intervention on the outcomes.

**BIBLIOGRAPHY**

Patrick S. Malone
the other, wealthy industrialist/financiers and European working classes. These social changes produced dislocations and inequalities that led to fears among established groups of moral and social danger. In the nineteenth century, following parallel developments in the advancing science of biology, social theory often used either biology (e.g., racial types) or biological analogies to the physical body and biological processes to explain the social system.

Émile Durkheim, a French sociologist, created the foundation for the modern sociological study of society by focusing on social facts, structures, and systems rather than individuals. His profound ideas generated many concepts and laid the basis for many fields of study. Like other foundational social theorists confronting rapid change, he privileged solidarity and cohesion as normal. Durkheim introduced two analogies for a smoothly functioning social order characterized by solidarity: the machine (mechanical) and the body (organic). He envisioned society as a system seeking equilibrium with norms for behavior. Anomie was a pathological condition of moral breakdown at the societal level.

Throughout the early twentieth century, this emphasis on social equilibrium or structural functionalism, further developed by such thinkers as Talcott Parsons, dominated U.S. social theory. In defining equilibrium and stasis (status quo) as desirable, it was implied that change and disorder were abnormal and threatening. These pathologies were not attributed to the differential nature and value of individuals but rather to aspects of structure. Nonetheless, such ideas emphasized the value of returning to the status quo over change.

The idea of declaring the behavior of individuals in particular social categories as socially pathological followed a different trajectory. In the post-Darwin nineteenth century, Darwin’s theories of evolutionary change were applied loosely in ways that misinterpreted his theory. Particular social categories or populations were seen as having an essential, innate, and immutable behavioral inferiority leading to criminal and dangerous behaviors. While Darwin saw natural selection occurring in a random, purposeless way with no implied hierarchy of worth, Social Darwinism saw different classes and races as arrayed in terms of inferiority and superiority.

The development of race studies occurred as new nation-states were restructured from former European imperial monarchies, creating a need to build national unity and loyalty among diverse citizens. This led to preoccupations with the dangers of difference and an interest in the scientific study of race. Throughout the new nations of Europe and in the United States, nascent disciplines emerged such as the now-repudiated anthropological “science” of race and the racially tinged science of criminology, which used race to predict and explain criminal behavior and justify policies of “social hygiene.” In the twentieth century, the racial ideas of scientific racism and criminology continued, especially in Germany. There they culminated in Nazi racial theory, which advocated a removal of categories of people defined as biologically debased, such as Jews, Gypsies, and homosexuals.

As such racial thinking was repudiated in the twentieth century, concepts of culture and cultural relativism, as well as concepts related to the self, psychic states, and personal identity, developed. Behaviors viewed as pathological for society relied less on innate racial attributes. While they continued to be associated with specific social categories, the new link between populations and pathology emphasized cultural learning and personal experience rather than biology. While biological attributes retained explanatory power for differences between genders and sexualities (e.g., homosexuality), behavioral pathologies were more associated with improper values, choices, and psychological states.

Ideas such as the culture of poverty first promulgated by Oscar Lewis blamed poor people for perpetuating their condition through inappropriate values and “weak ego structures.” A whole series of “social pathologies,” from dependence on welfare to substance abuse and inner-city gang violence, were linked to having learned improper values through substandard parenting in single-parent households. Yet these explanations, which blamed specific populations for social pathology, merely replaced racial determinism with cultural determinism.

Because stability and order are privileged as natural and normal and the profound and rapid social changes of recent decades are relegated to the sphere of the abnormal and dangerous, people who are the most disadvantaged and excluded in dominant ideologies and representations, such as single mothers ("welfare queens"), nonwhites, and nonheterosexuals, are blamed for their own situations. They also function as popular scapegoats for broader social problems and “moral decline.” In this way, they carry the weight of social problems not only through their personal circumstances of material and political deprivation but also through their symbolic representation as stigmatized and despised people.

Social science critiques of the culture of poverty examine ways to represent poor people as varied individuals with competence and awareness who cannot be categorized in terms of innate biology or culture. Particular behaviors of the poor can be analyzed in terms of the extremely constrained options of disadvantaged social positions, as rational strategies, or as political opposition rather than social pathology.

Moreover, in the second half of the twentieth century U.S. sociologists such as C. Wright Mills and William Ryan began to point out the role that dominant elite
interests play in defining normalcy and pathology as the status quo as well as the way this masks the relationship between structural relations of power and the social production of inequality. Blaming the victims (stigmatized and disadvantaged groups such as the poor) was shown to not only hide the effects of power and privilege but also to stifle recognition of a need to address social problems through sociopolitical change. Late-twentieth-century European social theories developed by such thinkers as Michel Foucault, Pierre Bourdieu, and others have brought issues of differential power and inequality to the fore. After continued world wars and the cold war as well as social movements advocating anticolonial independence, socialism, feminism, and civil and human rights, these ideas have emerged and have led to reexamining the ideological uses of social pathology as a way of reinforcing current inequalities in the social order.

PATINKIN, DON
1922–1995

Don Patinkin was born in Chicago on January 8, 1922, to Russian Jewish immigrants, and he died in Jerusalem on August 6, 1995. His main contribution was the integration of the theories of value and money developed in Money, Interest, and Prices, the most influential book on monetary macroeconomics in the 1950s and 1960s. That book grew out of Patinkin’s PhD thesis, submitted to the University of Chicago in 1947 after an academic year as research assistant at the Cowles Commission for Economic Research, where he interacted with well-known economists such as Lawrence Klein, Kenneth Arrow, Trygve Haavelmo, and Jacob Marschak, among others. In 1949, after a brief period as assistant and associate professor at the Universities of Chicago (1947–1948) and Illinois (1948–1949) respectively, Patinkin moved to Israel to take up a position as lecturer in the newly created department of economics at the Hebrew University, where he stayed until the end of his life. Apart from his academic appointments at the university (as full professor after 1957 and emeritus after 1989), Patinkin also served as the first director of the Maurice Falk Institute for Economic Research in Israel from 1956 to 1972.

REAL BALANCE EFFECT

Patinkin’s 1956 book may be regarded as the most important contribution to the neo-Walrasian synthesis (named after French economist Léon Walras)—that is, the attempt to build the theoretical framework of macroeconomics on a developed general equilibrium system—after John Hicks’s 1939 Value and Capital. The process of adjustment to equilibrium was firmly grounded by Patinkin on the “method of successive approximation,” Walras’s theory of tatonnement, which had been largely neglected in the literature. Together with Paul A. Samuelson’s stability analysis, the tatonnement provided the backbone of Patinkin’s discussion of how the market solves the excess-demand equations. He criticized traditional “classical” monetary analysis for assuming that the equations of excess demand for goods determine relative prices (called the “homogeneity postulate”), while the price level is determined by the equation of exchange in the market for money. Partly motivated by the work of his former Chicago teacher Oskar Lange, Patinkin showed that this “dichotomization” of the economy into real and monetary sectors was logically inconsistent. In particular he was the first to realize that if the demand for money depended on the price level then—because of the budget constraint of agents—the demand for goods also depended on that level. Logical consistency required that the equations of excess demand for goods include real money balances as an argument in the individual utility functions, named “real balance effect” by Patinkin. The invalid dichotomization described above should be, according to Patinkin, distinguished from the “valid dichotomy” between the real and monetary sectors, expressed by the quantity theory of money as formulated.
in his book: Under the assumption the agents are free of money illusion, changes in the quantity of money affect only nominal variables and leave the equilibrium value of real variables unaffected (i.e., money is neutral in the long-run).

Although the stabilizing effect of changes in the price level on real balances and, therefore, on aggregate demand had been discussed before, specifically by Gottfried Haberler in his 1937 book *Prosperity and Depression* and by A. C. Pigou in his 1943 article “The Classical Stationary State,” they did not work out its implications for the integration of monetary and value theory. According to Harry G. Johnson in his 1962 article “Monetary Theory and Policy,” Patinkin’s criticism of classical monetary theory sparked off a debate about the accuracy of his historical account and the import of his theoretical claims, known as “the Patinkin controversy.” A few years later, Frank Hahn argued in his 1965 article “On Some Problems of Proving the Existence of an Equilibrium in a Monetary Economy,” that Patinkin left unsolved a fundamental problem of monetary theory: to prove the existence of a general equilibrium with a positive value for money.

**DISEQUILIBRIUM MACROECONOMICS**

Patinkin’s second main theme was the contrast between the Keynesian model (named after British economist John Maynard Keynes)—where markets do not clear and quantities respond to quantities—and the Walrasian system, which assumes that trades are only made at a market-clearing price vector. According to Patinkin, unemployment is a disequilibrium phenomenon that should be understood as the result of the effect of aggregate demand constraint on the behavior of firms and workers. Patinkin’s disequilibrium analysis of the labor market, with both firms and workers off their respective labor demand and labor supply curves, was later complemented by Robert W. Clower’s analogous interpretation of consumption as a function of income in the goods market in his 1965 publication “The Keynesian Counter-Revolution: A Theoretical Appraisal.” In their 1971 article “A General Disequilibrium Model of Income and Employment,” Robert J. Barro and Herschel I. Grossman combined Patinkin’s and Clower’s analyses in a fixed-price model that quickly became the most influential exposition of disequilibrium macroeconomics. It was largely thanks to the Barro-Grossman model—which may be regarded as an outgrowth of chapter 13 of *Money, Interest, and Prices*—that Patinkin’s approach to unemployment finally penetrated the macroeconomic literature. After this theoretical contribution to Keynesian economics, Patinkin became engaged in the 1970s and 1980s in an extensive investigation of the historical development of Keynes’s thought. He concluded that the “central message” of Keynes’s macroeconomics was the role of changes in aggregate income in bringing the goods market to less than full employment equilibrium, based on the assumption that the marginal propensity to consume is less than one.

**PATINKIN’S IMPACT**

Patinkin’s search for the microfoundations of macroeconomics has had a deep impact on economic theory. His contribution to the money-in-the-utility-function approach has become part of modern monetary theory mainly through the work of Miguel Sidrauski (1967). Although the real balance effect has lost space to substitution effects in monetary economics—its acceptance nowadays depends on the theoretical assumption that the intertemporal utility function is not separable in consumption and money balances, and on the empirical evidence about its size at business-cycle frequencies—according to Richard J. Sweeney (1988) and Peter N. Ireland (2005) it still plays a role as part of the broader wealth effect in models with specified intertemporal budget constraints and forward looking agents. In the same vein, despite the diminishing interest on disequilibrium macroeconomics since the late 1970s, Patinkin’s pathbreaking search for the compatibility of macroeconomics and microeconomics has left its mark on the research agenda of Keynesian and neoclassical economists alike.

Patriarchy

Patriarchy is a social structural phenomenon in which males have the privilege of dominance over females, both visibly and subliminally. This phenomenon is manifested in the values, attitudes, customs, expectations, and institutions of the society, and it is maintained through the process of socialization. Some societies are more patriarchal than others, but virtually all are characterized by the phenomenon in one form or another. Patriarchy is a function of male physical, social, economic, and political power. Females and children, along with any individuals with a nontraditional gender identity, suffer from subordination to men.

The term patriarchy comes from the Latin pater (father) and arch (rule). Historically, “rule of the father” was the more appropriate definition of patriarchy. Valentine Moghadam has written that under classic patriarchy, “the senior man has authority over everyone else in the family, including younger men, and women are subject to distinct forms of control and subordination” (2004, p. 141). Furthermore, property, residence, and descent all proceed exclusively through the male line. Today, however, this definition may be considered an overly simplistic description because the phenomenon has evolved substantially over time.

As already mentioned, to varying degrees, patriarchy is nearly universally prevalent. Although, as Gerda Lerner (1986) has noted, anthropologists have found societies in which sexual differences are not associated with practices of dominance or subordination, patriarchy does exist in the majority of societies. Often, patriarchy is associated more strongly with nations characterized by religious fundamentalism. Yet male domination and female subordination are salient features of social structure in virtually all societies, regardless of the race, ethnicity, class, or religion of the members. Most patriarchal societies have adopted characteristics associated with male domination, namely, aggression and power, as well as the consequences of these characteristics, namely, war and destruction.

Because the subordination of women to men is a feature in the majority of all societies, patriarchy is often argued to be due to biology, such as women’s principal role in childbearing. However, many scholars today hold that patriarchy is a social construction. Lerner has written that there are indeed biological differences between men and women, but “the values and implications based on [those differences] are the result of culture” (1986, p. 6).

The existence of patriarchy may be traced back to ancient times. Lerner has stated that the commodification of women’s sexual and reproductive capacity emerged at about the same time as the development of private property, thus setting the stage for patriarchal social structures. The Bible is sometimes cited as exemplifying the original

SECONDARY WORKS

Mauro Boianovsky
“father-rule” form of patriarchy in many of its stories. An example is the Adam and Eve story of creation, in which Adam is created first, followed by all the animals. Then Eve is created from part of Adam so that, in a sense, he may be considered her parent (Pateman 1989, p. 451). As such, Adam is clearly in the dominant position. This is consistent with Lerner’s explanation that “men learned to institute dominance and hierarchy over other people by their earlier practice of dominance over the women of their own group” (1986, p. 9). The sexual subordination of women was subsequently written into the earliest system of laws, enforced by the state, and secured by the cooperation of women through such means as “force, economic dependency on the male head of the family, class privileges bestowed upon conforming and dependent women of the upper classes, and the artificially created division of women into respectable and not-respectable women” (Lerner 1986, p. 9).

The classic form of patriarchy decreased in its prevalence during the seventeenth century. The transition to what Teresa Meade and Pamela Haag have described as a broader fraternal-right patriarchy or “domination of society by the ‘brotherhood of men’ ” (1998, p. 92) is often associated with the rise of “capitalist rationalism” because the prior standard of fathers ruling over sons was not compatible with the demands of capitalism. Meade and Haag also note that “the defeat of classic patriarchy in the Enlightenment era meant that the father’s absolute power over sons was lost and patriarchy moved to the broader civil society” (1998, p. 92). This transformation occurred to the detriment of women whose work in the home was suddenly separated from what was considered to be the larger economy.

Modern patriarchy is structural, meaning that it underlies the foundations of all of society’s institutions. In most societies, any accomplishments in the direction of gender equality must be made within a larger patriarchal structure. This is one reason why women are at such a constant disadvantage socially, politically, and economically. In the world today, the vast majority of leaders are men. Moreover, Laura Bierema has noted that while women make up over half the workforce, they fall far short of men in terms of pay, promotions, benefits, and other economic rewards. She has also observed that those women who are successful economically often reach their goals by emulating men, thus reproducing the masculine traits and characteristics that are associated with success. By doing so, the patriarchal systems “that discriminate against women and people of color” are reinforced (Bierema 2003, p. 3). Those women who actually become world leaders or advance to high positions in the business world tend often to do so on terms that accommodate the needs and characteristics of males, hence necessitating the need for them to make significant sacrifices (e.g., having a family versus a career). Otherwise they would be viewed as distinctly different from their male peers, and this would be disadvantageous.

PATRICIANS

The word patrician is an adjective derived from the Latin word for “father,” which was also a term for a senator. In the later republic of the second and first centuries BCE, certain families were recognized as patrician by their distinctive clothing and the reservation of certain priesthood positions for them. The Roman historical tradition (formed in the third and second centuries BCE) held that patricians consisted of families granted this title at various times during the Roman kingdom and that these families had a monopoly on political office at the start of the republic. There ensued a long political conflict known as the Struggle of the Orders, in which non-patricians, known individually as the plebeians and collectively as the plebs, sought to attain the redress of economic grievances and the right to hold office. The upshot was that in the period from c. 367–c. 287 BCE the patrician monopoly of office holding was broken. The wealthy plebeian families then fused with the patricians to form a ruling class known as the nobility.

Examination of the list of the earliest chief magistrates of the republic (the consuls) shows that the traditional story of the origin of the patricians cannot be true. For the first half century of the republic (starting c. 509 BCE), a number of families that were later of plebeian status appear among the consuls. It is only from around 450 BCE onward that patricians tend to monopolize the office, and this monopoly seems established by the end of the
400s. It is a phenomenon attestable elsewhere (e.g., the city-states of Archaic Greece and the free cities of late medieval Germany) for the office-holding families of a given period to establish for themselves a legal monopoly on office, a situation that eventually breaks down as some of the monopolizing families fall into economic decline while new families attain wealth and wish to end the monopoly.

While some Roman patricians eventually sank into obscurity, a number of the most prominent senatorial families of the mid- and late republic were of patrician status, and this status conferred great prestige. The patricians suffered many deaths during the civil wars that saw the decline of the republic (88–31 BCE) and ushered in the autocratic form of government known as the Roman Empire. There were not enough patricians to fill the priesthood positions reserved for them. Both Julius Caesar (c. 100–44 BCE) and his adopted son Augustus, the first emperor (ruled 27 BCE–14 CE), were authorized to create new patrician families (from prominent senatorial families of plebeian status). As part of his effort to conceal his power by restoring some of the forms (but not the substance) of the old republican government, Augustus promoted the careers of the remaining patricians. The old patrician families continued their decline as they died out naturally and fell victim to prosecution under the Julio-Claudian emperors, and the emperors continued to create new patricians. Men with this status enjoyed swifter advancement in their careers, but the status died out in the third century.

**PATRIOTISM**

The word *patriotism* derives from the Latin *patria*, meaning “country.” Patriots are citizens joined by a love of country and a readiness to sacrifice, perhaps even die, for their country. Such patriotism was emphatically characteristic of the Spartans of classical antiquity. They were citizens in the strict sense of the term: They shared an identity with others to whom they were related by nationality, as well as by blood, and a sense of belonging to a community for which they bore responsibility. In a word, they were public-spirited.

The Spartans’ sense of public-spiritedness did not develop by accident. Spartan boys were trained, almost from birth, to be soldiers, and Spartan girls were required to exercise naked (in public), with a view to producing sons capable of being soldiers, as well as daughters capable of giving birth to them. Their readiness to fight (and perhaps give their lives) for their country is best exemplified by the legendary King Leonidas and the three hundred Spartan soldiers who fought the Persians and died at Thermopylae in 480 BCE. For good reason, then, the word *Spartan* has come to be associated with *patriot*.

In one respect at least, it was easy for Spartans to be patriots, easier than it would prove to be for later generations of Greeks, or Europeans generally. Spartans could be for their city without reservation or equivocation, because there was nothing else in Sparta to be for: no gods other than the city’s gods, and no life other than the life in and provided by the city. As George Grote suggests, the subordination of the individual to the state has had no parallel in the history of the world.

The likes of Sparta were surely not to be found anywhere in the West after the advent of Christianity. By effecting a separation of the “things that are Caesar’s” and the “things that are God’s,” Christianity made it more likely that a person’s loyalties would be divided, and sometimes come into conflict.

Such conflict became even more likely after Martin Luther (1483–1546) launched the Reformation. Before Luther, there had been one church, but now there were several: Lutherans and Calvinists, as well as Roman Catholic. This development had political consequences. Could a devout Roman Catholic such as Thomas More (1478–1535) obey his sovereign, Henry VIII (1491–1547), after the sovereign broke with the papacy in Rome? Could the Calvinist (or Presbyterian) Scots obey their king, Charles I (1600–1649), who commanded them to worship according to the Anglican Book of Common Prayer? Not likely and, in the event, impossible; the pious More preferred the scaffold and the stubborn Scots a civil war.

The seventeenth century was not a propitious time for the making of patriots. Almost everywhere in Europe, the rulers were princes and the people subjects, not citizens. This may explain why the first recorded use in English of the word *patriotism* did not occur until 1726, when it was defined as “public-spiritedness.” Generally speaking, only citizens (not subjects) could be expected to be public-spirited.
Thus, patriotism became linked with the rise of popular sovereignty. This development, in turn, depended on the discovery or pronouncement of new universal and revolutionary principles respecting the rights of man—see, for example, Thomas Hobbes’s *Leviathan* (1651) and John Locke’s *Two Treatises of Government* (c. 1690). From these new principles came new governments—first in America, then in France—and with them a new understanding of patriotism, or an understanding other than the sort of filial piety associated with Sparta.

Alexis de Tocqueville (1805–1859) was the first to recognize this new form of patriotism, or at least to speak of it. In his *Democracy in America* (1835–1840), Tocqueville argued that this patriotism was more rational than the simple love of one’s native land; this patriotism, he said, was “born of enlightenment” and grows with “the exercise of rights.” Abraham Lincoln (1809–1865), in his 1852 eulogy on the American statesman Henry Clay (1777–1852), declared that Clay “loved his country partly because it was his own country, but mostly because it was a free country; and he [worked zealously] for its advancement, prosperity and glory, because he saw in such the advancement, prosperity and glory of human liberty, human rights, and human nature.” (Lincoln [1852] 1989, p. 264). There is nothing parochial about this patriotism: Lincoln made that very plain. Clay is praised not so much for loving his country, but rather for loving the *idea* of his country, or its principles. Those principles are scientific and, therefore, universal principles. Any country might adopt them.

This was of particular concern to Edmund Burke (1729–1797), the Anglo-Irish statesman and political theorist. He understood that the French Revolution (1789–1799) was something new and (to him) something alarming, especially because its principles appeared to be readily exportable; those abstract, scientific, and universal principles, if exported—and unleavened by the unique experiences or traditions of a country—would reduce not only the French but the people of all Europe to “one homogenous mass.”

Something like this did in fact begin to happen, but the French Revolution, and what Pierre Manent has called the enormous Napoleonic enterprise, “unleashed a contrary movement of particularization and national separation” (Manent 1998, p. 187). In a word, the attempt to export these universal principles gave rise to the glorification of the nation, which is to say, nationalism and a politics of ethnicity, where what matters is blood, not the political principles associated with patriotism. “I speak for Germans simply, of Germans simply,” said the philosopher Johann Fichte (1762–1814) in 1807, a sentiment repeated by many another Europeans (Fichte 1807, p. 3).

Since then, in intellectual circles, the very idea of the nation—as well as that of patriotism—has been discredited. This process began in 1848 when Karl Marx (1818–1883) declared in *The Communist Manifesto* that “working men have no country” (Marx and Engels [1848] 1932), and they would refuse to fight for country. This proved not to be true when World War I broke out in 1914. Then, after World War II (1939–1945), Europeans set about the task of divesting themselves of their sovereignty in favor of the European Union. It remains to be seen if the citizens of the European Union will love it, let alone fight for it.

It seems that patriotism has become unfashionable among some intellectuals. One prominent American university professor, Martha Nussbaum, suggests that the times require that people get rid of patriotism and, to that end, become citizens of the world and lovers of humanity. But humanity does not have a government, and there is no reason to believe that, if it had a government, it would be lovable.

**PATRONAGE**

The term *patronage* describes the practice of distributing public sector posts in exchange for political support. In the absence of binding civil service rules, a party boss...
(patron) rewards loyal partisans (clients) by providing them with public sector employment. Patronage therefore can be included among a broad range of clientelistic political practices in which parties use public resources to deliver private and club benefits to particular groups of voters in order to maximize electoral support. Different from other types of clientelistic practices, patronage provides the client with a steady source of income whose stability depends on the reelection of the patron.

To successfully develop a patronage system requires: (1) the selection of political leaders through elections, (2) mass adult suffrage, (3) a high degree of electoral competition within or between parties, and (4) weak civil service rules. The first three requirements—elections, mass political participation, and party competition—lead to increasing demands on political elites by their core constituency. In the absence of civil service rules, the distribution of public sector posts becomes an appealing strategy that ties the survival of the voter (client) to the survival of the party boss (patron).

Because patrons can only sustain a limited number of clients, two crucial functions of the patronage exchange are the selection and monitoring of clients. In selecting clients, patrons seek to either maintain their vote or to expand it. For maintaining their vote, patrons target loyal voters. For expanding their vote, patrons target swing voters and invest considerable more resources in monitoring the patronage exchange. The practice of patronage is intimately connected to the rise of political machines specialized in organizing and allocating political influence by controlling the supply of public sector jobs and by monitoring the vote of large constituencies. Because the cement that binds the patron and the client is not ideological, political allegiance to the machine is based on the distribution of particularistic, material rewards over different types of political personnel.

A widespread political phenomenon, patronage is also known in the United States by the term spoils system, where the “spoils” of the political system go to the “victor” of the electoral contest. The spoils system that emerged during the Gilded Age was eventually dismantled by the enactment of the Pendleton Act in 1883 and the creation of the Civil Service Commission, which introduced meritocratic rules for the recruitment and promotion of public service employees. The introduction of these rules significantly reduced the available pool of public jobs that political machines could allocate to voters. Such reforms also weakened the political grip of party bosses, such as William M. “Boss” Tweed in New York, Huey P. Long Jr. in Louisiana, and Edward H. Crump in Chicago. Since the late twentieth century, as an increasing number of countries have democratized, comparative scholars have emphasized the negative consequences of patronage for the development of an independent citizenship capable of holding politicians accountable for their performance in office.

**PAVLOV, IVAN**

**1849–1936**

Ivan Petrovich Pavlov, a Russian physiologist, received a Nobel Prize for his experimental studies of the interactions of gastrointestinal secretions with the activities of the pancreas and other glands. His observations on the role of the nervous system led him to explore what he called “psychic reflexes”—secretions of stomach acids elicited not by food itself but by stimuli such as the smells or tastes preceding food ingestion. He is best known for this discovery of conditioned, or conditional, reflexes and his subsequent experimental analyses of them. He created preparations using the salivary glands of dogs in which he could conveniently measure salivation elicited by metronomes or other arbitrary stimuli presented in various temporal relations to subsequent food deliveries.

Research inspired by Pavlov’s work has been extended to applications such as the modification of emotional responding through behavior therapies. Pavlov was a principled scientist and an outspoken critic of the Soviet system in Russia, and it is unfortunate that brainwashing and other coercive methods have sometimes been attributed to his influence. These attributions are inappropriate and inaccurate because such methods are neither procedurally nor historically derivative of Pavlov’s scientific contributions.
PAVLov’S LIFE

Pavlov was the son of a parish priest. Some personal characteristics appeared early and remained with him throughout his life: a passion for physical work (especially in the garden), a love of books and learning, and an unshakable integrity. His experience in working with his hands stood him in good stead later in the speed, efficiency, and delicacy of his surgical skills. His readings led him to chemistry and biology, and he came to regard as two of his intellectual heroes the physiologist Ivan M. Sechenov (1829–1905), for construing conscious as well as unconscious activity as reflexes of the brain, and the naturalist Charles Darwin (1809–1882), for his theory of natural selection. Pavlov attended a religious seminary but in 1870 dropped theology in favor of physiology and then a medical degree in Saint Petersburg. In 1881 he married Seraphema (Sara) Vasilievna. They raised two sons, Vladimir and Vselvolod, and a daughter, Vera (a third son, Mirchik, died as a child). Sara was both devout and devoted to Pavlov, and he envied her religious faith.

After completing his dissertation, Pavlov studied in Germany and then began independent research on cardiac physiology in the Saint Petersburg laboratory of the physiologist Sergei P. Botkin (1832–1889), who soon entrusted the direction of his laboratory to Pavlov. This allowed Pavlov to devote all of his time to research. He involved himself thoroughly in all details of an experiment and even in his earliest experimental work regarded it as essential to work with the intact organism in order to maintain as far as possible the natural conditions of the physiological systems he chose to study. He had no patience with people with motives other than knowledge, such as those who saw research as a way to satisfy nonscientific agendas. The motto in Pavlov’s laboratory was “Observation and observation,” and he meant the direct observation of nature itself, not what someone had written about it.

Pavlov received his Nobel Prize in 1904. By the time of the Russian Revolution in 1917, his international reputation protected him from external intrusions on his research. Though he did not study the nervous system directly, he interpreted his findings in terms of changes in the irradiation of brain areas and attempted to extend his thinking to theories of language and of psychiatric disorders such as psychoses. In contrast to his contributions in physiology and conditioning, these theories did not fare well.

Pavlov maintained regular schedules of activity throughout his life, including outdoor exercise in the form of games and swims. Even during Joseph Stalin’s purges, he was outspoken in his denunciation of the Communist system, going so far as refusing admission to his laboratory to the Communist commissar of education and writing a letter of criticism to Stalin. Pavlov worked in his Saint Petersburg laboratory until shortly before his death of pneumonia in February 1936.

PAVLov’S WORK

The term conditioned, from the Russian phrase for “conditioned reflexes,” might better have been translated as “conditional,” because the name was applied to reflexes conditional upon relations among stimuli. In respondent conditioning, one stimulus, the conditional stimulus (CS), signals the presentation of another, the unconditional stimulus (US). The responses respectively elicited by these stimuli are the conditional response (CR) and the unconditional response (UR). Pavlov’s conditioned salivary reflexes provide the prototypical example. When an originally neutral bell repeatedly signals food in the mouth of a hungry dog, it becomes a CS as salivation begins to be elicited by this signaling stimulus as well as by the US, the food itself.

Ironically, Pavlov may never have used a bell in his experiments; his rare mention of bells occurs only in later work, where it probably refers to electrically operated devices. The ubiquitous references to Pavlov’s bell probably originated with a common example of a conditioned reflex in popular writings about Pavlov’s research: a dinner bell eliciting salivation in those called to the table (Pavlov’s own bell was kept on his desk, presumably for summoning servants).

Pavlov’s conditioning procedure has been called “respondent,” “Pavlovian,” and “classical conditioning,” distinguishing it from procedures studied especially by the American psychologists Edward L. Thorndike (1874–1949) and later B. F. Skinner (1904–1990). In Pavlov’s procedure the important features are the relations between two stimuli, whereas in Thorndike’s and Skinner’s instrumental or operant procedures they are the relations between a stimulus and the response that has produced it.

Pavlov arranged various temporal relations between the CS and the US. For example, in both trace and delay conditioning, a relatively long time elapsed between CS and US; they were distinguished by whether the CS turned off or remained present in the interim. In both types conditional responding began shortly after the start of the CS, but with successive trials it gradually moved closer to the time of the US. Trace conditioning acquired its name from Pavlov’s assumption that the CS had to leave some trace in the nervous system to be effective.

Attention to Pavlovian conditioning followed from how easily it could be related to the concept of association, a learning principle with substantial precedent in philosophy and psychology. Learning was said to take place through associations of ideas, and conditional
reflexes seemed to represent a primitive example of their formation. In a kind of mental chemistry, ideas were thought to be associated through such properties as having common elements or occurring together in time. Thus conditioning was regarded as at the root of all learning.

During Pavlov’s lifetime, conditioning was seen as a sort of stimulus substitution in which, through CS-US pairing, the CS acquires power to elicit the UR. But it is now clear that this account misrepresents what happens in at least three ways. First, conditioning depends not on CS-US pairings but rather on whether the CS predicts the US. If the CS is as often followed by no US as by the US, the two are often paired, but conditioning does not occur because the CS does not predict a US delivery. Second, in many preparations the CR differs in form or other properties from the UR. For example, with an intravenous opiate as the US, the CR is a diminished pain threshold, whereas the UR is a heightened pain threshold; the CS does not substitute for the US (similarly, if a metronome becomes a CS, the dog does not try to eat it). Third, preparations in which the typical latency between US and UR is long enough that a CS can be presented after the US but either before or after the UR show that conditioning depends on the CS-UR rather than the CS-US sequence. Conditioning occurs as long as the CS precedes the UR, so the relation of the CS to responding is more important than its relation to stimuli.

PAX BRITANNICA
Usually applied to the era between the end of the Napoleonic Wars in 1815 and the start of World War I in 1914, the term Pax Britannica has both geopolitical and economic connotations. That period, in contrast to preceding and subsequent periods, was comparatively free of military conflict between major powers (with notable exceptions: the Crimean War, the Franco-Prussian War, the Spanish-American War, and the Russo-Japanese War). It was also relatively free of full-blown trade wars. Britain was unquestionably the strongest country, militarily and economically. But there is no consensus among international relations scholars and economists over the extent to which British power and statecraft should be credited with the century-long "pax."

The idealized picture of Pax Britannica features nineteenth-century England as a benign global hegemon, providing the international public goods of peace and unrestricted commerce primarily through the instrumentality of its superior navy and (after the repeal of the protectionist Corn Laws in 1832) its policy of international free trade. The realist version roots the policies of naval superiority and global free trade in the self-interest of an industrializing island country dependent on a far-flung empire of raw-material producers.

Successive British governments employed the navy and the country’s economic power to intimidate, if not coerce, nations—not only in the British Empire but also sovereign states—to open up their ports and domestic markets to British goods and investors. Nor was Britain willing to tolerate challengers to its ability to “rule the waves.” Determined to maintain a fleet capable of defeating the combined fleets of any two countries, London took umbrage at Berlin’s decision in the 1890s to significantly augment the German navy in order to support the kaiser’s growing imperial appetite. In response, Britain entered into spheres-of-influence agreements with France to preempt German ambitions in Africa and elsewhere.

In theory, not only did Britain’s free trade policy require the peace (which the Royal Navy was supposed to enforce), but also unrestricted global commerce, as conceptualized by Adam Smith (1723–1790), David Ricardo (1772–1823), and their disciples, would itself advance world peace. Free trade would deepen the interdependence of nations—each of which, according to the principle of comparative advantage, would specialize in producing most efficiently products that would advance the commonweal. But by the start of the twentieth century, with other major powers seeking, like Britain, to comprehensively industrialize and to modernize their militaries, mercantilistic rivalries again became the order of the day, and Pax Britannica was now widely castigated as a cover for unbridled British imperialism.

Peace

Peace is a key concept in the social sciences and a central concern in the field of international relations. There is much focus on peace in the world with many entities working to promote or to protect peace. At the same time, there are many disagreements surrounding it. Definitions of peace, traditional explanations of peace between states, intrastate wars, reconciliation, and the role of third parties are discussed below.

Definitions

Peace is often defined as the absence of violence. However, there is considerable disagreement over what forms of violence need to be absent. This disagreement is reflected in the list of winners of the Nobel Peace Prize, which includes statesmen, such as U.S. secretary of state Henry Kissinger (the 1973 laureate along with Le Duc Tho of Vietnam); spiritual leaders, such as the fourteenth Dalai Lama, Tenzin Gyatso (the 1989 laureate); and various international organizations. These actors have made vastly different contributions to world peace, and their recognition as Nobel laureates demonstrates the diversity of opinion on what peace is and how it is promoted.

In the social sciences, some scholars of peace, such as Johan Galtung of Norway, maintain that peace needs to encompass equality, socioeconomic factors, and social justice. In fact, there is a growing interest in the role of non-violent social movements, particularly in struggles for equality in domestic political situations, in achieving and maintaining peace. A more minimalist definition of peace focuses on the absence of physical, primarily military, violence between political entities, particularly states. This latter definition lies at the heart of the criticism seen in some circles for the choice of Kenyan Wangari Maathai as the 2004 Nobel Peace Prize laureate for her work in sustainable development and environmentalism.

For the most part, social science research has focused on the absence of military violence when discussing peace. This is particularly true for international relations scholars who were influenced by the tone of the cold war and the major interstate wars of the twentieth century.

Traditional Schools of Thought

Liberalism and realism, the dominant schools of thought in peace studies and international relations, both accept that anarchy (which is defined in international relations as the lack of a central government) is a major concern for states. However, these schools diverge on the implications of this situation on interstate cooperation and conflict. Peace studies also encompasses various lines of thoughts, with such emphases as Marxism (capitalism), feminism (gender), and constructivism (identity and meanings).

One finding that has received much attention is that democracies do not go to war with each other. Researchers trace this argument back to the views of the German philosopher Immanuel Kant (1724–1804) in his essay “Towards Perpetual Peace” (1795), and today it is identified with the liberal school of thought. This type of “democratic peace” has received much support in countless empirical studies, as well as consideration from policy circles, particularly in the West. A democratic country is essentially in a state of stable peace—that is, military violence against another democracy is removed as an option from the mindsets of leaders. In some parts of the world, this status extends to entire regions, as illustrated by pluralistic security communities such as exist in contemporary western Europe. Developments in western Europe, specifically the formation of the European Union, highlight other important elements that are identified with Kant’s vision of what it takes to attain peace, such as economic development, economic ties with other countries, and international organizations.

There is another school of thought where the focus is on the role of alliances, threats, and power. This approach falls primarily within the power politics or “realist” school in international relations. Thus, in the case of western Europe, external threats and powerful opponents, particularly the Soviet Union, contributed to the coming together of European countries after World War II (1939–1945). In this view, peace emerges when there is a balance of power. That is, power deters power and in the process maintains the peace. Some have even argued that...
a world in which more states possess nuclear weapons might result in less bloodshed.

WARS
As shown above, the traditional schools of thought have much to say about interstate peace and war. Although some scholars suggest that interstate wars are becoming obsolete, states continue to justify the need to use violence for survival as seen in interactions between developed and developing countries. In contrast, there is little expectation that intrastate wars—that is, civil wars—may become obsolete.

Intrastate wars are more common than interstate wars, and they result in greater devastation. Civilians are particularly vulnerable in intrastate wars, and the international system has been more averse to intervening in such conflicts. Periods of respite after such wars are short, as many actors involved in intrastate conflicts return to fighting because wars leave people with few options. For this reason, there are growing calls for attention to development and institution building after intrastate wars.

Conflicts over control of governments and territory tend to play central roles in warfare. In a positive development, the international community since the end of World War II has generally not recognized territorial aggrandizement attempts. However, international norms change over time and there is no guarantee that this situation will last. Disagreements among major powers over the “rules” of the game are of particular importance because considerable global violence may occur when powerful countries are no longer satisfied with the rules and act more unilaterally.

LEVELS OF PEACE AND RECONCILIATION
There is an increasing focus on improving relations following hostility between political units. In this regard, it is useful to identify varying levels of peace. A “low level” of peace between former belligerents describes a situation where there is little more than a halt to fighting—that is, a “frozen war.” In contrast, a “high level” of peace encompasses institutionalization of relations and mutually beneficial interactions between former opponents. This approach is related to the topic of reconciliation, which involves the study of how harmonious relations come about after extensive violence.

Particularly important in reconciliation is the willingness of former opponents to improve their relations. In this regard, leadership plays a crucial role. Leaders who would rather rally the public against a former foe for domestic political gain certainly do not contribute to the improvement of relations. Leaders in democracies face a tougher atmosphere because domestic opposition can be particularly fierce and hard to ignore. As such, former warmongers have sometimes played important roles in improving relations with an opponent because their credentials lead to the belief that they will defend vital interests. One of the potential reasons for this change in heart toward a former foe is the presence of a greater security threat.

Postwar relations are influenced by the war itself and may set in motion a cycle of violence. Existing empirical research suggests that the contents of the terms of peace treaties influence the prospects for future violence. This is true for both interstate and intrastate wars. However, an important difference between interstate and intrastate wars is that forgiveness and truth-seeking play a more central role in contributing to intrastate reconciliation.

This difference brings to the forefront the positions of morality and power. Can there be peace without justice? Can peace be imposed? The lack of an international tribunal with significant authority limits what can be expected. Justice has been a major issue following interstate wars, where public trials may occur. Yet the fear of going back to war, weak judiciaries, and the complicated task of determining culprits has resulted in the generous distribution of amnesty, and societies often seem willing to accept less than full justice. After interstate wars, justice is even more tied to power, as the defeated are the only ones on trial. This situation generally arises when one side is able to impose its will on the other, and in some contexts such impositions have been followed by the attainment of high levels of peace between states, as occurred following World War II. Yet an imposition of peace by an imperial force, a party in a civil war, or an international force is generally associated with a low level of peace and an eventual return to arms.

THIRD PARTIES
There is a considerable role for third parties. Some countries have contributed to United Nations peacekeeping operations, which have traditionally acted to keep belligerents away from each other after a cease-fire without taking sides and generally with the prior consent of the opposing parties. Third-party military (and police) deployment is particularly important after intrastate war situations where there is much suspicion and where former belligerents are likely to interpret the moves of the other as hostile and take actions to increase their security that are likely to make the other side fear them, a situation known as a security dilemma. While peacekeeping is fairly uncontroversial, such actions have had mixed records. Other third-party efforts, such as peace enforcement, are more hotly debated because they involve coercing the opposing sides to stop fighting through the use of massive
force. Most of the time, third-party military involvement occurs after considerable violence has already taken place, but since the 1990s there has been a shift toward preventive diplomacy. Such efforts include the United Nations Preventive Deployment Force in Macedonia, which was deployed in early 1993 before a breakdown into chaos emerged.

Not all third-party efforts involve military might. Nongovernmental organizations play a role in socioeconomic development and in strengthening institutions and building ties before and after violence. In addition, while many entities work out their differences through bilateral means, there are other options, including adjudication and mediation. Yet, as with many other aspects that characterize attempts to foster peace, mediation does not guarantee success, given the array of elements to consider, such as timing and leverage.

Thus, the study of peace continues. Much more is understood about peace as the absence of military violence. At the same time, there is still much to be done in the area of reconciliation and in efforts to formulate a broader definition of peace.

**PEACE MOVEMENTS**

In scholarly literature and public discourse, the term *peace movement* is often used as a synonym for pacifism. But in discussing peace movements, it is helpful to differentiate between the periods before and after 1945. Since World War II, peace movements have had distinctively new patterns of mobilization and organization, and many of them have been protests against certain wars or armaments, but not necessarily against violence or the military per se.

In sociological terms, peace movements can be defined as social movements that aim to protest against the perceived dangers of political decision-making about armaments, military alliances, and war. They stress the possibly violent fallout from these decisions (which the decision makers perceive as mere risk), and advocate non-violent solutions. For these purposes, they use a variety of communication media and public performances of both an instrumental and a symbolic nature. It is one of the distinctive features of peace movements in the contemporary media society that their capacity for mobilization depends to a large degree on their resonance in public opinion and in the mass media, and that many of their protests are primarily calculated with regard to public reaction. As social or protest movements, peace movements evolved at least since the 1960s together with environmental and women’s movements, often including considerable overlap and cross-fertilization in terms of aims, ideologies, institutional networks, and individual supporters.

**SOCIOCOLOGICAL APPROACHES**

According to Thorsten Bonacker and Lars Schmitt in their 2004 study, both historical and sociological research on peace movements reflects the conceptual changes within the “social movement”-approach from the 1970s to the present. Frank Parkin’s 1968 study was one of the first interpretations of the British Campaign for Nuclear Disarmament (CND). Here he analyzed it in terms of its social constituency as a form of “middle class radicalism.” This focus on the social characteristics of protest actors ties in with the concept of a value change from materialistic (i.e., working-class) to post-materialistic (i.e. middle-class) values as a key prerequisite for peace movement mobilization. The empirical validity of this concept has been repeatedly challenged.

During the 1980s many studies relied on the “resource mobilization” concept and tried, with a focus on the organizational capacities of protest elites, to identify the successes or failures of peace movement mobilization. Much historical research in this fashion tended to conceptualize the history of armaments and warmongering in the simplifying dichotomy of “doves” and “hawks,” and to exaggerate the impact of peace protests on decision-making processes, without putting this issue under careful scrutiny. Peace movements since 1945 have, in fact, yielded their most substantial results not in opposition against any particular war, but in turning forms of civil unrest and nonviolent disobedience into a legitimate means of political mobilization. They have thus broadened, together with the feminist and environmental
movements, the scope of democratic participation in American, European, and some Asian societies.

Since the 1990s constructivist approaches have gained currency in both sociological and historical research on peace movements. These concepts do not focus on the social resources of collective actors or on the political system as an external variable for movement mobilization. Rather, they stress the importance of the protests themselves as communicative events and the capacity of these events to construct reasons for protest through the attribution of possible dangerous consequences to political decisions. According to Michael S. Foley in his 2003 book *Confronting the War Machine: Draft Resistance during the Vietnam War*, characteristic elements of peace movements are in this perspective performative forms of protest, particularly those that use the bodies of the protesters to display their personal commitment and consternation, as in the draft resistance movement against the Vietnam War.

Another important feature is the moralistic codes of protest communication with its stark, sometimes eschatological or bleak dichotomies, which accentuate the difference between risk/danger, either/or. Constructivist approaches stress the importance of frames—collective semantic patterns that provide a coherent interpretation of social reality—for the transformation of latent conflicts into manifest peace protests. In a 1992 article Jürgen Gerhards and Dieter Rucht differentiate between *diagnostic* frames (what is the problem?), *prognostic* frames (how can it be solved?), and *motivational* frames, which trigger and channel the protest communication. According to this approach, “masterframes” are necessary to make the identity of protest communication plausible and visible and to determine its place in the context of society.

**PROTESTS AGAINST NUCLEAR WEAPONS DURING THE 1950s AND 1960s**

Peace mobilization after 1945 was mainly triggered and influenced by the dangers and the unprecedented destructive potential of nuclear technology, unleashed for the first time in the atomic bombings of the cities of Hiroshima and Nagasaki in August 1945. Particularly during the first postwar decade, mobilization against atomic armaments fell prey to the emerging cold war confrontation between the military blocs in the East and West. Communist parties worldwide were quick to seize the opportunity. The World Congress of Intellectuals for Peace met in the Polish city of Wrocław in August 1948 and was the first in a string of carefully orchestrated meetings meant to demonstrate the genuinely peace-loving policies of the socialist countries and to launch vitriolic attacks against the United States.

Toward the end of the 1950s, non-aligned protest movements against the possession, proliferation, testing, and employment of nuclear weapons gained momentum in various Western European countries. CND was founded in February 1958 by leading left-wing intellectuals such as the philosopher Bertrand Russell (1872–1970) and the historian A. J. P. Taylor (1906–1990). Its basic tactic was to renew the pressure on the parliamentary Labour Party to advocate unilateral disarmament with the means of extra-parliamentary public protest. From the early 1960s CND also adopted the aim of Britain’s exit from the North Atlantic Treaty Organization (NATO, a military alliance of countries in Europe and North America). CND and subsequent movements in other countries professed a concern for peace as a global issue and for “humanity” as its subject. But in its rhetoric and commitment, the respective nation state remained the focal point. Antinuclear peace activism was thus an international, but not a strictly transnational, movement, as were later the campaigns against the Vietnam War and the Euromissiles.

CND invented and employed an annual march from the nuclear weapons facility in Aldermaston, England, to London during the Easter weekend as the major form of public protest. This example was subsequently added to the symbolic repertoire of peace movements in various European countries, as was the symbol of a circle encompassing a broken cross, representing the semaphore signals for the *a* and *d* of “nuclear disarmament.” The tactics and symbols of CND were copied and emulated in many Western European countries, but also in southern Europe, for example in Greece.

**THE ANTI-VIETNAM WAR MOVEMENT**

Both Catholic and Communist circles in France had already protested against the attempts of the French military to regain control over the Democratic Republic of Vietnam (which was founded in 1945 in the northern part of the former French colony) since 1946. But the fate of the Vietnamese people became a focal point for massive antiwar mobilization in western European countries, Japan, and the United States only after the U.S. army had started massive attacks against the operations of the communist guerrilla NFL in South Vietnam and a systematic aerial bombing of North Vietnam in 1964 and 1965. The Norwegian Solidarity Committee for Vietnam established in December 1965 was among the first concerted efforts to organize material support for the people in North Vietnam and to call for a peaceful solution of the conflict. As similar committees and movements in other countries, it demanded an immediate stop of the American aerial bombing and the strict application of the Geneva Accords.
of 1954, which had divided Vietnam with a demilitarized zone around a demarcation line along the seventeenth degree of latitude. Whereas these aims could still be supported by pacifist groups such as the War Resisters International, they remained distant from the subsequent radicalization of antiwar protests, particularly its relation to the use of violence. With a peak during the years from 1967 to 1970, the anti-Vietnam War movement attracted a large, but also highly volatile, group of followers particularly among the student population in Europe, Japan, and the United States, which was involved in parallel protests against the system of higher education, the “establishment,” and the anti-Communist postwar consensus in their respective countries and U.S. “imperialism” in the Third World.

The radicalization of the movement made its position with regard to the use of violence ambivalent. A growing number of antiwar protesters not only supported a military victory of the NFL, but showed also a readiness for the use of violence in clashes with the police during rallies. More generally, confrontational tactics and the calculated use of spectacular protest forms such as sit-ins, the locking of persons to buildings, or the burning of national flags were almost without precedent in the history of peace activism. Only the Committee of 100, a group of radicals that had separated itself from CND in 1960, had already practiced spectacular sit-downs of protesters in Whitehall, England, or at missile sites and had attracted a lot of media coverage with these actions. With the trend toward only loosely coordinated and more disruptive forms of public protest, the mobilization against the Vietnam War indicated a major shift in the organizational patterns and tactics of peace movements in the United States, Europe, and Japan. It thus marked a major change in the history of peace movement mobilization.

PROTESTS AGAINST EUROMISSILES DURING THE 1980s
In December 1979 NATO finalized its “double track solution” for intermediate range nuclear missiles, which combined an offer to the Soviet Union to negotiate a reduction or elimination of nuclear missiles in Europe with the announcement to deploy cruise missiles and Pershing II missiles in five Western European nations in the autumn of 1983. This decision offered, paradoxically, an unprecedented window of opportunity for peace movement mobilization, which gained momentum in all Western European countries by the spring of 1981. France was the only exception, due to the domestic consensus about the need to maintain its own nuclear weapons arsenal. The protests against the Euromissiles were not organized or orchestrated by some of the established or freshly mushrooming organizations of peace activists—according to an estimate about 2,300 local, national, and international groups in 1982—but only loosely coordinated in a network structure. A major attempt for transnational coordination on the European level was European Nuclear Disarmament (END), founded by the historian E. P. Thompson and other veteran members of the British peace movement in April 1980. Mobilization against the Euromissiles reached its peak between June 1982 and October 1983, when the movement organized protest marches with several hundred thousand participants each in various European capital cities. Even during this climactic period, though, the peace movement was not able, with the one exception of Greece, to gather a majority of the population behind its major aim, a unilateral nuclear disarmament of NATO.

The tactics of the Euromissiles movement included two distinctive features. In contrast to the antinuclear protests of the 1950s and 1960s, this wave of mobilization did not so much employ famous novelists or intellectuals as popular figureheads and symbolic icons, but brought a new generation of experts from the sciences to the forefront. Physicians and physicists in particular briefed the mass media about the dangers of nuclear weapons and about their environmental consequences. This gradual shift from a moral to a more cognitive approach went together with a policy orientation of the Euromissiles movement. More than earlier peace movements, these new activists tried to engage in a dialogue with the respective governments about possible alternatives to existing defense policies. The public discourse of the Euromissiles campaign was highly gendered and contrasted the “male power craziness” of “Reagan-Haig-Weinberger” (then the U.S. president and two of his leading cabinet members) with the need for a more feminine empowerment in favor of peaceful solutions, encapsulated in the slogan “Petting instead of Pershing.” Both as a cultural current and a political aversion, anti-Americanism provided a masterframe for the peace movements of the 1980s in Western Europe and Japan. American peace movements since the 1950s made, on the other hand, much effort to describe their activities as the embodiment of the genuine progressive tendencies of American identity and popular culture, to avoid accusations of being “un-American.”

Starting in the late 1970s, an independent peace movement emerged also in the Warsaw Pact countries (those in Eastern Europe), although only on a limited scale and in constant fear of police repression. Groups such as the Moscow Trust Group in the Soviet Union, Charter 77 in Czechoslovakia, and the Protestant peace groups assembled behind the slogan “swords into ploughshares.” They organized meetings and distributed unauthorized literature. Their basic aim was to restore elements of an unregulated civil society by nonviolent means and to foster a “détente from below,” after the Helsinki
Agreement on Security and Cooperation had ratified détente, or an easing of tensions, between the Eastern and Western bloc countries in 1975.

PEACE PROCESS

A peace process is a series of persistent diplomatic and political initiatives to negotiate a resolution to a protracted conflict between political entities. The term was first used consistently during the 1970s to describe the efforts to negotiate peace agreements between Israel and its Arab neighbors. Its use has spread since, both geographically and across social categories. Peace process today, thus, can refer to an interstate conflict (e.g., India and Pakistan); to a conflict between a state and some politically defined group within it, such as an ethnic (e.g., South Africa and its black population), religious (e.g., Sudan and its Christian south), or ideological movement (e.g., Guatemala and the Guatemalan National Revolutionary Unity); or to a conflict between two such opposing groups within a state (e.g., Catholics and Protestants in Northern Ireland).

Aside from the protagonists, other actors are often involved, in various roles, in peace processes. Third parties in peace processes can be divided into two types. The first are weak and, at least ostensibly, neutral actors. These actors could be states (e.g., Norway in its role in the Oslo Accords between Israel and the Palestine Liberation Organization, as well as in the negotiation between the Sri Lankan government and the Tamil Tigers), nongovernmental organizations (e.g., the International Committee of the Red Cross, which is often involved in negotiations, though usually with regard to cease-fires and interim measures, not comprehensive peace agreements), or even some individuals (e.g., former U.S. president Jimmy Carter and former South African president Nelson Mandela). Although such actors are not necessarily devoid of self-interest (in boosting their prestige, for instance), they are usually perceived as nonpartisan, and therein lies their strength as peace facilitators. Weak and neutral third parties are most likely to succeed in cases where the main task involves coordination of the protagonists and supply of “good offices” (i.e., the venue for talks, facilities needed, and the diplomatic channels).

Weak actors, however, are limited in their ability to foster peace when the protagonists’ positions are far apart and where mere coordination is not enough. In such cases, the involvement of the second type of mediator—a global or regional power—is often needed to enable a successful peace process. The role of the United States in the Egyptian-Israeli peace is a good example of a global power involvement, and Syria’s centrality to negotiation of the 1989 Taif Accord among the warring factions in Lebanon is an example of the role a regional power has played in peacemaking. A power-wielding international organization can also play a similar role, although it usually requires the backing of strong states in such an effort. NATO in the Balkans and the Organization of American States in El Salvador have both played such a role.

Powerful third parties usually have more tools at their disposal than do weaker ones when it comes to peace negotiations, because they can bring to bear their own resources and power in order to pressure the sides towards agreement and, if necessary, to enforce their compliance with the agreements (by creating, funding, or manning verification mechanisms, or by involving their own prestige and supplying security guarantees for the agreement’s
implementation). To be sure, global or regional powers are less likely to be neutral in conflicts, as their more immediate self-interests are more likely to come into play, but neutrality is not always a necessary condition for successful third-party mediation. Instead, it is very important that third parties are willing to invest time, energy, prestige, and sometimes money in the peace process. They also should be willing to pressure both parties, including their allies, to make compromises and comply with agreements.

A peace process typically involves four phases. The first phase, prenegotiation, often held secretly, deals with setting the agenda for the negotiation. The second phase usually involves a cease-fire and perhaps other acts of good will, such as prisoner exchange or a return of forces to a status-quo-ante position. The third phase is the negotiation phase, which, ideally, ends in a formal peace accord. In the last phase, the parties to the agreement are required to implement their share. Although this schedule is useful for analytical purposes, the reality, of course, is much more complicated. Phases are often mixed or overlap. Whereas the Egyptian-Israeli peace process more or less followed this classic program, for instance, the Palestinian-Israeli process has a more complex structure, with many phases of negotiations and interim agreements.

Time is a crucial factor in a peace process, as the gradual pace of the process allows for construction of “confidence building measures” in order to increase mutual trust. It also allows both parties to climb down from their war-creating rhetoric and start educating their people about the possible dividends of peace. In practice, however, the record of success of peace processes is not too encouraging: At least as many processes fail as succeed, and it is hard to distinguish a success from a temporary truce.

In a sense, this relatively poor success rate for peace processes is to be expected. Most of the cases in which a peace process is tried are very protracted and complex conflicts that are, by definition, hard to solve. There are also reasons intrinsic to the idea of the peace process that make it vulnerable to failure. First, the mere term peace process raises expectations in the protagonists’ populations, and when progress is slow (e.g., if violence continues or the economic dividends of peace are not forthcoming), it can be difficult to secure the support of a frustrated population. Second, in order to gain approval for the process in their respective communities, leaders often exaggerate the benefits and gloss over the pitfalls of the process. Finally, another major reason for the failure of peace processes is the role of “spoilers,” those actors in the two opposing camps who see peace as a threat to their positions or their interests. Spoilers are able to sour the peace process by playing on the public’s frustrations. Moreover, the structure of negotiations, especially in cases that postpone the final accord to the end of the process, is such that the leaders often have strategic incentives to cooperate with their own spoilers as a way of pressuring their opponents to give up more concessions.

None of these problems should suggest that peace processes should be abandoned altogether, but just that they should be approached carefully, with caution not to raise expectations too high, and with a structure that minimizes the opportunities for the spoilers. One option would be to establish an accord about the final shape of the peace early on in the process, while designing a gradual and verifiable implementation to allow for trust to rebuild.

PEACEFUL COEXISTENCE

During the cold war the Soviet Union and China developed the concept of peaceful coexistence as a mechanism for communist states to coexist with capitalist states and, in the case of China, with regional powers. It was in direct contrast with theories of mutual antagonistic aggression that supposed the two regimes could not live in peace. However it was applied differently by the Soviet Union and the People’s Republic of China and debates over differing interpretations of peaceful coexistence contributed to one aspect of the Sino-Soviet split in the 1950s and 1960s. Since the end of the cold war, peaceful coexistence has been used to describe proposed solutions to the Arab-Israeli conflict in the Middle East, Wall Street’s view of regional instability following the Asian financial crisis of the late 1990s, relations between the West and Islam, relations between Jews and Christians and Muslims, and relations among the different Christian churches. The
concept of peaceful coexistence has been adopted by many international documents and has become a widely accepted norm of international relations.

THE INTERPRETATION OF THE SOVIET UNION

Vladimir Lenin, revolutionary leader, head of the Communist Party, and first premier of the Soviet Union, first put forth the concept of peaceful coexistence after the Bolshevik Revolution in Russia in 1917. At that time he issued a Decree on Peace that called for World War I (1914–1918) participants to immediately open negotiations for peace. Leon Trotsky, the people’s commissar of foreign affairs, followed this decree by proclaiming an official doctrine of peaceful coexistence with all peoples. However, in the early years of the Soviet Union the doctrine of world revolution was also proclaimed, especially by Lenin. The two policies, peaceful coexistence and world revolution, would appear to conflict for several decades.

In 1943 Joseph Stalin dissolved the Comintern and disbanded the Communist International, a Moscow-based organization of communist parties around the world that promoted revolution. This action was an attempt to appease the Western allies during World War II (1939–1945) and secure a wartime pact, but was ultimately a precursor to the formal adoption of peaceful coexistence as a part of Soviet foreign policy. In 1949, still under Stalin’s leadership, the Soviet Union founded the World Peace Council to organize a global peace movement to promote the concept of peaceful coexistence internationally. This was meant to assuage Western concerns that the Soviet Union was driven by world revolution, as had been advocated by the Bolsheviks.

Nikita Khrushchev first fully enunciated peaceful coexistence following the Twentieth Congress of the Soviet Communist Party when he denounced crimes committed by Stalin. As Soviet premier, beginning in 1953 Khrushchev promoted the concept of peaceful coexistence as a way to ease tensions between the Soviet Union and the United States in light of the possibility of nuclear war. Beginning in 1956 peaceful coexistence was proclaimed the cornerstone of Soviet foreign policy. For the Soviet Union peaceful coexistence had one main assertion: that the United States and the Soviet Union and their respective ideologies could co-exist together without war. It had three elements: socialism in one country (the total commitment of Soviet resources in the home country, first introduced by Stalin in 1924); the Iron Curtain (sealing off the people of the Communist world from the people of the capitalist world); and the arms race (with military might substituting for political struggle). Khrushchev argued that while socialism would eventually triumph over capitalism this would occur without war, which was neither necessary nor inevitable.

Khrushchev explained the doctrine of peaceful coexistence as early as 1957 in a speech at the Albanian Embassy. In 1960 in an address to the United Nations General Assembly, Khrushchev underlined the policy: “The peoples of the Soviet Union and the Soviet Government are striving unremittingly to have the principles of peaceful coexistence firmly established in relations between States.... The policy of peaceful coexistence assumes a readiness to solve all outstanding issues without resort to force, by means of negotiations and reasonable compromises.” The reasoning behind the policy was Khrushchev’s aim to “catch up and overtake” the West in economic development, and thereby prove the superiority of the Soviet system. In a speech to the Supreme Soviet on October 31, 1959, Khrushchev explained that conflict between the two systems, communist and capitalist, must be resolved, and that peaceful coexistence was a real method to this end based on human society.

In a 1959 article in the prominent American journal *Foreign Affairs* Khrushchev offered American readers a detailed exposition of the Soviet viewpoint, and maintained that the Soviet Union professed a policy of peaceful coexistence since its creation following the revolution in 1917: “From its very inception,” Khrushchev argued, “the Soviet state proclaimed peaceful coexistence as the basic principle of its foreign policy. It was no accident that the very first state act of the Soviet power was the decree on peace, the decree on the cessation of the bloody war” (Khrushchev 1959, p. 1). Khrushchev tried to demonstrate his commitment to peaceful coexistence by participating in international peace conferences such as the Geneva Summit, and by traveling internationally, such as visiting Camp David in the United States in 1959.

The Soviet Union applied the concept of peaceful coexistence to its relations with industrialized countries, particularly its relations with the United States and relations between member countries of the North Atlantic Treaty Organization (NATO) and Warsaw Pact member countries (also termed the Communist Bloc in Eastern Europe).

THE INTERPRETATION OF THE PEOPLE’S REPUBLIC OF CHINA

During the 1960s and 1970s China applied the concept of peaceful coexistence to its relations with nonsocialist countries in the developing world while arguing that a belligerent attitude should be maintained toward “imperialist” capitalist countries. In the early 1980s China extended its interpretation of the concept of peaceful coexistence to include its relations with all countries, including capitalist countries.
In December 1953, during negotiations with India over Tibet, Chinese premier Zhou Enlai (1898–1976) proposed the Five Principles of Peaceful Coexistence. These were written into the Agreement Between the People’s Republic of China and the Republic of India on Trade and Intercourse Between the Tibet Region of China and India signed in April 1954 by Zhou Enlai and Indian prime minister Jawaharlal Nehru following the Sino-Indian War in Tibet. The Five Principles were reiterated by Zhou in 1954 in joint declarations issued with the prime ministers of India and Myanmar during Zhou’s visit to the two countries in June 1954, and again at the Bandung Conference of 1955, the first conference of Asian and African countries, where they were incorporated into the conference declarations. In 1982 the Five Principles were written into the Constitution of the People’s Republic of China as applied to all sovereign nations. The Five Principles of Peaceful Coexistence as promoted by China are:

- Mutual respect for sovereignty and territorial integrity (government free from external control)
- Mutual nonaggression
- Noninterference in each other’s internal affairs
- Equality
- Mutual benefit

There are three notable consequences of the Chinese concept of peaceful coexistence, as differentiated from the Soviet concept of peaceful coexistence. First, the Chinese concept includes the expansion of free trade. Second, the Chinese concept emphasizes national sovereignty, territorial integrity, and noninterference in internal affairs; thus American moves to promote democracy and human rights are seen as hostile actions. Third, the concept precludes support of Communist insurgents in other countries. One major consequence of this policy was that China would not support Communist insurgencies in Southeast Asia, particularly Indonesia and Malaysia, and would distance itself from overseas Chinese in those nations. The Chinese concept of peaceful coexistence does not extend to Taiwan, which is considered a part of China and thus an internal affair in which other nations, particularly the United States, should not interfere.

The concept of peaceful coexistence remains a part of Chinese foreign policy in the beginning of the twenty-first century. On September 3, 2005, Chinese president Hu Jintao called for promoting peaceful coexistence of different civilizations to draw upon each other’s strengths.

PEANUT INDUSTRY

Peanut (Latin, *Arachis hypogaea*, *Fabaceae*), often referred to as groundnut, is a leguminous plant that produces fruit below ground. The growth habit of the peanut is indeterminate, indicating that vegetative and reproductive growth occur simultaneously on the same plant throughout a significant period of the plant’s life cycle. Peanut gynophores, which ultimately produce kernels enclosed by pods, are born above ground and move to the soil due to physiological processes where development and maturation occurs. Three botanical classifications of peanuts include Virginia, Spanish, and Valencia, which vary in vegetative and reproductive morphology. Pod and kernel size of peanuts belonging to these botanical classifications influence utilization and marketing.

Peanuts originated in South America in the region of northern Argentina, Bolivia, and Paraguay. Domestication of peanuts occurred slowly, in a manner similar to that of many other crop plants. During the early colonial period peanuts moved from South America to other areas, and they are now grown in many regions of the world, most notably Argentina, China, India, Indonesia, numerous countries in Africa, and the United States. Production per unit land area varies considerably across regions, and is affected by climate; soil and natural resources; production, pest management, and storage technology and capacity; management skills; and stability of governments and key infrastructure.

Peanut kernels contain 35 to 55 percent triacylglycerols (fresh weight) and 21 to 36 percent protein. Carbohydrate constitutes approximately 15 percent of peanuts, and key vitamins including ascorbic acid, niacin, riboflavin, and thiamin are found in peanuts. In addition to the positive attributes of peanut nutrition, peanuts act as an allergen in some segments of the human population.
The nutritive value and possible allergic reaction influence peanut utilization and marketing.

The primary use of the peanut is for oil production. Peanuts are also used for human consumption in pastes and peanut butter, snack foods including a component in candies, and direct consumption with little to no additional processing after harvest. In developing countries, peanuts often are consumed directly or used as a component in local diets. In countries with intricate marketing systems, peanuts are often shelled, blanched, roasted, and in some cases salted. Components originating from these processes are also used in nonfood categories. However, its uses as oil and in products for direct human consumption are by far the most important uses of peanuts around the world.

The noted scientist George Washington Carver (c. 1864–1943) was responsible for an explosion in the number of uses for peanuts while he worked at the Tuskegee Institute in the United States. Over his distinguished career, Carver developed numerous uses and products derived from or containing peanuts. Perhaps the most notable product he helped introduce to a large segment of the population was peanut butter, which accounts for approximately half of peanut utilization in the United States. These products were important in establishing markets and supporting rural farming communities, and in combating poverty around the world, especially with respect to child development and health.

Production practices vary considerably around the world. In many regions of Africa, peanuts are produced at subsistence levels, yielding less than 1,000 kg/ha, using slash-and-burn techniques. In other regions, peanut yields can exceed 6,000 kg/ha when managed with intensive fertility and pest-management programs using modern machinery, and scientifically based principles and technology. Peanuts are susceptible to a wide range of insect and disease pests, nematodes, and weed interference, and they require essential elements, most notably calcium, and fertile soils with adequate drainage, to optimize yield. Because peanuts are consumed directly by humans, with limited post-harvest processing, it is important that peanut farmers develop strategies to minimize human and environmental exposure to pesticides.

Because peanuts are considered a staple in many regions of the world, the nutritive value of peanuts offers the possibility of its cultivation as a cash crop for local, regional, national, and international trade. In many countries, especially the United States, peanuts are grown primarily for domestic consumption. In contrast, some countries such as Argentina export a high percentage of peanuts produced domestically. Government legislation and farm programs, as well as regional agreements such as the North American Free Trade Agreement (NAFTA) and more inclusive agreements such as GATT (General Agreement on Tariffs and Trade), affect domestic and export marketing of peanuts. Relationships between the three major segments of the peanut industry—farmers, shellers, and manufacturers—can be complex and at times strained in free-market economies.

Peanuts have long been a key component of human diets around the world, especially with respect to providing oil and essential protein and vitamins, and they continue to be a staple food source, especially in rural regions of developing countries. Ensuring that final peanut products do not contain aflatoxin, a mycotoxin caused by the organism *Aspergillus flavus*, is important to protect human health. Additional research and education designed to minimize the negative effects of peanut allergens are also important in the utilization and marketing of peanuts. Increasing technology development and transfer to increase yield, improve quality, and minimize storage loss will continue to be important as human populations rise and concerns over environmental impacts increase. Developing fair-trade agreements and arrangements between major peanut-producing countries, especially those with export potential, is a continuing challenge.

PEARL HARBOR

In the 1920s and 1930s, Americans had become strongly isolationist, many believing that America’s involvement in World War I (1914–1918) had been a political mistake. Moreover, the Great Depression focused people’s attention on the economy. Against this backdrop, the U.S. Congress had passed neutrality acts in 1935 and 1936. The tipping point that rallied public opinion toward involvement in World War II (1939–1945) came on December 7, 1941.

The Japanese leadership had sought to drive U.S. and U.K. forces out of Asia. To Japan, the attack on Pearl Harbor was seen as merely a “strategic necessity”—part of the grand strategy to secure the Pacific for oil shipments to fuel the empire’s efforts to dominate Asia. However, as history has shown, the plan backfired.

In the attack, 21 American ships were sunk or badly damaged, 188 planes were lost, and 155 planes were damaged. In addition, 2,403 American lives were lost and 1,178 persons injured. Fortunately for the U.S. Navy, no aircraft carriers were in port. While the attack produced a substantial military loss, the main effect of the attack was to crystallize Americans’ public opinion against the Axis Powers. On December 8, 1941, the United States declared war on Japan.

Prior to the attack on Pearl Harbor, President Franklin Delano Roosevelt had battled with Congress to expand American support for England’s struggle against Germany. But once Americans saw themselves as victims, resistance to entering the war melted away. German führer Adolf Hitler’s declaration of war against the United States on December 11, 1941, provided the linkage necessary to associate pro-war sentiment generated by Pearl Harbor to Germany, and the United States declared war on Germany and Italy on the same day.

Public sentiment toward Japanese Americans was low prior to the attack at Pearl Harbor, as evidenced by the 1924 Immigration Act that halted Japanese immigration. The attack on Pearl Harbor sparked war hysteria. In 1942 Roosevelt signed Executive Order 9066, which authorized the internment of 120,000 individuals of Japanese ancestry, two-thirds of whom were U.S. citizens. These people were removed from their homes along the West Coast and relocated to inland camps.

President Roosevelt declared December 7 “a date that will live in infamy.” As a term, “Pearl Harbor” has come to represent foreign treachery, the perils of U.S. isolationism, and of potential vulnerability of American military forces. The specter of Pearl Harbor helped to fuel the nuclear arms race between the United States and Union of Soviet Socialist Republics during the twentieth century. But Pearl Harbor also constrained U.S. power. Robert Kennedy persuaded his brother, President John F. Kennedy, not to execute a surprise air strike against Cuba during the 1962 Missile Crisis because it would appear to the world as “Pearl Harbor in reverse.”

In Japan, the attack is sometimes viewed as the mistake that awoke a “sleeping giant.” Others associate it with a dishonorable period of aggression in the nation’s history.

Though Pearl Harbor happened more than sixty years ago, the incident carries a great deal of weight in American political rhetoric. Political analysts and media personnel compared the terrorist attacks on the United States of September 11, 2001, to Pearl Harbor. While similar in some respects, the Pearl Harbor analogy, along with other thinly veiled language such as “axis of evil,” permitted President George W. Bush to build support for the War on Terror by framing it in terms reminiscent of World War II.

PEARSON, KARL

Karl Pearson was one of the principal architects of the modern theory of mathematical statistics. His interests ranged from mathematical physics, astronomy, philosophy, history, literature, socialism, and the law to
Darwinism, evolutionary biology, heredity, Mendelism, eugenics, medicine, anthropology, and crainometry. His major contribution, however, by his lights and by posterity’s, was to establish and advance the discipline of mathematical statistics.

The second son of William Pearson and Fanny Smith, Carl Pearson was born in London on March 27, 1857. In 1879 the University of Heidelberg changed the spelling of his name when it enrolled him as “Karl Pearson”; five years later he adopted this variant of his name and eventually became known as “KP.” His mother came from a family of seamen and mariners, and his father was a barrister and Queen’s Counsel. The Pearsons were a family of dissenters and of Quaker stock. By the time Carl was twenty-two he had rejected Christianity and adopted “Freethought” as a nonreligious faith that was grounded in science.

Pearson graduated with honors in mathematics from King’s College, Cambridge University in January 1879. He stayed in Cambridge to work in Professor James Stuart’s engineering workshop and to study philosophy in preparation for his trip to Germany in April. His time in Germany was a period of self-discovery, philosophically and professionally. Around this time, he began to write The New Werther, an epistolary novel on idealism and materialism, published in 1880 under the pseudonym of Loki (a mischievous Scandinavian god). In Heidelberg Pearson abandoned Karl philosophy because “it made him miserable and would have led him to short-cut his career” (Karl Pearson, Letter to Robert Parker, 17 August 1879. Archive reference number: NW/Cor.23. Helga Hacker Pearson papers within Karl Pearson’s archival material held at University College London). Though he considered becoming a mathematical physicist, he discarded this idea because he “was not a born genius” (Karl Pearson, Letter to Robert Parker, 19 October 1879. Archive reference number:922. Karl Pearson’s archival material held at University College London). He stayed in Berlin and attended lectures on Roman international law and philosophy.

He returned to London and studied law at Lincoln’s Inn at the Royal Courts of Justice. He was called to the bar at the end of 1881 but practiced for only a very short time. Instead, he began to lecture on socialism, Karl Marx, Ferdinand Lassalle, and Martin Luther from 1880 to 1881, while also writing on medieval German folklore and literature and contributing hymns to the Socialist Song Book. In the course of his lifetime, he produced more than 650 publications, of which 400 were statistical; over a period of twenty-eight years he founded and edited six academic journals, of which Biometrika is the best known.

Having received the Chair of Mechanism and Applied Mathematics at University College London (UCL) in June 1884, Pearson taught mathematical physics, hydrodynamics, magnetism, electricity, and elasticity to engineering students. Soon after, he was asked to edit and complete William Kingdom Clifford’s The Common Sense of Exact Science (1885) and Isaac Todhunter’s History of the Theory of Elasticity (1886).

THE GRESHAM LECTURES ON STATISTICS

Pearson was a founding member of the Men’s and Women’s Club, established in 1885 for the free and unrestrained discussion of all matters concerning relationships of men and women. Among the various members was Marie Sharpe, whom he married in June 1890. They had three children, Sigrid, Helga and Egon. Six months after his marriage, he took up another teaching post in the Gresham Chair of Geometry at Gresham College in the City of London (the financial district), which he held for three years concurrently with his post at UCL. From February 1891 to November 1893, Pearson delivered thirty-eight lectures.

These lectures were aimed at a nonacademic audience. Pearson wanted to introduce them to a way of thinking that would influence how they made sense of the physical world. While his first eight lectures formed the basis of his book The Grammar of Science, the remaining thirty dealt with statistics because he thought this audience would understand insurance, commerce, and trade statistics and could relate to games of chance involving Monte Carlo roulette, lotteries, dice, and coins. In 1891 he introduced the histogram (a type of bar chart), and he devised the standard deviation and the variance (to measure statistical variation) in 1893. Pearson’s early Gresham lectures on statistics were influenced by the work of Francis Ysidro Edgeworth, William Stanley Jevons, and John Venn.

Pearson’s last twelve Gresham lectures signified a turning point in his career owing to the Darwinian zoologist W. F. R. Weldon (1860–1906), who was interested in using a statistical approach for problems of Darwinian evolution. Their emphasis on Darwinian population of species, underpinned by biological variation, not only implied the necessity of systematically measuring variation but also prompted the reconceptualization of a new statistical methodology, which led eventually to the creation of the Biometric School at University College London in 1894. Earlier vital and social statisticians were mainly interested in calculating averages and were not concerned with measuring statistical variation.

Pearson adapted the mathematics of mechanics, using the method of moments to construct a new statistical system to interpret Weldon’s asymmetrical distributions, since no such system existed at the time. Using the method of moments, Pearson established four parameters...
for curve fitting to show how data clustered (the mean), and spread (the standard deviation), if there were a loss of symmetry (skewness), and if the shape of the distribution was peaked or flat (kurtosis). These four parameters describe the essential characteristics of any empirical distribution and made it possible to analyze data that resulted in various-shaped distributions.

By the time Pearson finished his statistical lectures in May 1894, he had provided the infrastructure of his statistical methodology. He began to teach statistics at University College in October. By 1895 he had worked out the mathematical properties of the product-moment correlation coefficient (which measures the relationship between two continuous variables) and simple regression (used for the linear prediction between two continuous variables). In 1896 he introduced a higher level of mathematics into statistical theory, the coefficient of variation, the standard error of estimate, multiple regression, and multiple correlation, and in 1899 he established scales of measurement for continuous and discrete variables. Pearson devised more than eighteen methods of correlation from 1896 to 1911, including the tetrachoric, polyboric, biserial, and triserial correlations and the phi coefficient. Inspired and supported by Weldon, Pearson’s major contributions to statistics were: (1) introducing standardized statistical data-management procedures to handle very large sets of data; (2) challenging the tyrannical acceptance of the normal curve as the only distribution on which to base the interpretation of statistical data; (3) providing a set of mathematical statistical tools for the analysis of statistical variation, and (4) professionalizing the discipline of mathematical statistics. Pearson was elected a Fellow of the Royal Society in 1896 and awarded its Darwin Medal in 1898.

Pearson’s ongoing work throughout the 1890s with curve fitting signified that he needed a criterion to determine how good the fit was. He continued to work on improving his methods until he devised his chi-square goodness of fit test in 1900 and introduced the concept of degrees of freedom. Although many other nineteenth-century scientists attempted to find a goodness of fit test, they did not give any underlying theoretical basis for their formulas, which Pearson managed to do. The overriding significance of this test meant that statisticians could use statistical methods that did not depend on the normal distribution to interpret their findings. Indeed, the chi-square goodness of fit test represented Pearson’s single most important contribution to the modern theory of statistics, for it raised substantially the practice of mathematical statistics. In 1904 Pearson established the chi-square statistic for discrete variables to be used in contingency tables. Pearson published his statistical innovations from his Gresham and UCL lectures in a set of twenty-three papers, “Mathematical Contributions to the Theory of Evolution,” principally in Royal Society publications from 1893 to 1916. He established the first degree course in statistics in Britain in 1915.

PEARSON’S FOUR LABORATORIES

In the twentieth century Pearson founded and managed four laboratories. He set up the Drapers’ Biometric Laboratory in 1903 with a grant from the Worshipful Drapers’ Company (who funded the laboratory until 1933). The methodology incorporated in this laboratory involved the use of his statistical methods and numerous instruments. The problems investigated by the biometricians included natural selection, Mendelian genetics and Galton’s law of ancestral inheritance, craniometry, physical anthropology, and theoretical aspects of mathematical statistics. A year after Pearson established the Biometric Laboratory, the Worshipful Drapers’ Company gave him a grant to launch an Astronomical Laboratory equipped with a transit circle and a four-inch equatorial refractor.

In 1907 Francis Galton (who was then eighty-five years old) wanted to step down as director of the Eugenics Record Office, which he had set up three years earlier; he asked Pearson to take over the office, which Pearson subsequently renamed the Galton Eugenics Laboratory. Pearson had, by then, spent the previous fourteen years developing the foundations of his statistical methodology. His work schedule was so demanding that he took on this role only as a personal favor to Galton. Because Pearson regarded his statistical methods as unsuitable for problems of eugenics, he further developed Galton’s actuarial death rates and family pedigrees for the methodology of the Eugenics Laboratory. The latter procedure led to his twenty-one-volume Treasury of Family Inheritance (1909–1930). In 1924 Pearson set up the Anthropometric Laboratory, made possible by a gift from his student, Ethel Elderton. When Galton died in January 1911, his estate was bequeathed to UCL and he named Pearson as the first professor of eugenics. The Drapers’ Biometric and the Galton Eugenics laboratories, which continued to function separately, became incorporated into the Department of Applied Statistics.

Although Pearson was a eugenicist, he eschewed eugenic policies. For him and his British contemporaries (e.g., Herbert Spencer, George Bernard Shaw, H. G. Wells, Marie Stopes, and Virginia Woolf), eugenics was principally a discourse about class, whereas in Germany and America the focus was on racial purity. The British were anxious that the country would be overrun by the poor unless their reproduction lessened; the middle classes were thus encouraged to have more children. In any case eugenics did not lead Pearson to develop any new statistical methods, nor did it play any role in the creation of his statistical methodology.
His wife, Marie Sharpe, died in 1928, and in 1929 he married Margaret Victoria Child, a co-worker in the Biometric Laboratory. Pearson was made Emeritus Professor in 1933 and given a room in the Zoology Department at UCL, which he used as the office for *Biometrika*. From his retirement until his death in 1936, he published thirty-four articles and notes and continued to edit *Biometrika*.

**SCHOLARSHIP ON PEARSON**

Pearson's statistical work and innovations, his philosophy and his ideas about Darwinism, evolutionary biology, Mendelism, eugenics, medicine, and elasticity have been of considerable interest to innumerable scientists and scholars for more than a century. Throughout the twentieth century, many commentators viewed Pearson as a disciple of Francis Galton who merely expanded Galton's ideas on correlation and regression. Consequently, a number of scholars have falsely assumed that Pearson's motivation for creating a new statistical methodology arose from problems of eugenics. Among writers who have taken this view are Daniel Kevles, Bernard Norton, Donald Mackenzie, Theodore Porter, Richard Soltoway, and Tukufu Zuberi. However, using substantial corroborative historical evidence in Pearson's archives, Eileen Magnello (1999) provided compelling documentation that Pearson not only managed the Drapers' Biometric and the Galton Eugenics laboratories separately but also that they occupied separate physical spaces, that he maintained separate financial accounts, that he established very different journals, and that he created two completely different methodologies. Moreover, he took on his work in the Eugenics Laboratory very reluctantly and wanted to relinquish the post after one year. Pearson emphasized to Galton that the sort of sociological problems that he was interested in pursuing for his eugenics program were markedly different from the research that was conducted in the Drapers' Biometric Laboratory.

Juxtaposing Pearson alongside Galton and eugenics has distorted the complexity and totality of Pearson's intellectual enterprises, since there was virtually no relationship between his research in “pure” statistics and his agenda for the eugenics movement. This long-established but misguided impression can be attributed to (1) an excessive reliance on secondary sources containing false assumptions, (2) the neglect of Pearson's voluminous archival material, (3) the use of a minute portion of his 600-plus published papers, (4) a conflation of some of Pearson's biometric and crainometric work with that of eugenics, and (5) a blatant misinterpretation and misrepresentation of Pearsonian statistics.

Continuing to link Galton with Pearson, Michael Bulmer (2003) suggested that the impetus to Pearson's statistics came from his reading of Galton's *Natural Inheritance*. However, Magnello (2004) argued that this view failed to take into account that Pearson's initial reaction to Galton's book in March 1889 was actually quite cautious. It was not until 1934, almost half a century later, when Pearson was 78 years old, that he reinterpreted the impact Galton's book had on his statistical work in a more favorable light—long after Pearson had established the foundations to modern statistics.

The central role that Weldon played in the development of Pearson's statistical program has been almost completely overlooked by most scholars, except for Robert Olby (1988) and Peter Bowler (2003), who gave Weldon greater priority than Galton in Pearson's development of mathematical statistics as it related to problems of evolutionary biology. Weldon's role in Pearson's early published statistical papers was acknowledged by Churchill Eisenhart (1974), Stephen Stigler (1986), and A. W. F. Edwards (1993). In all her papers, Magnello addressed Weldon's pivotal role in enabling Pearson to construct a new mathematically based statistical methodology.

Norton (1978a, 1978b) and Porter (2004) argue that Pearson's iconoclastic and positivistic *Grammar of Science* played a role in the development of Pearson's statistical work. However, Magnello (1999, 2005a) disputed this and argued that while *The Grammar of Science* represents his philosophy of science as a young adult, it does not reveal everything about his thinking and ideas, especially those in connection with his development of mathematical statistics. Thus, she maintains, it is not helpful to see this book as an account of what Pearson was to do throughout the remaining forty-two years of his working life.

Although long-standing claims have been made by various commentators throughout the twentieth and early twenty-first centuries that Pearson rejected Mendelism, Magnello (1998) showed that Pearson did not reject Mendelism completely but that he accepted the fundamental idea for discontinuous variation. Moreover, Philip Sloan (2000) argued that the biometricians’ debates clarified issues in Mendelism that otherwise might not have been developed with the rigor that they were to achieve.

Additionally, virtually all historians of science have failed to acknowledge that Pearson’s and Galton’s ideas, methods, and outlook on statistics were profoundly different. However, Bowler (2003) detected differences in their statistical thinking because of their different interpretations of evolution, and Stigler acknowledged their diverse approaches to statistics in his *The History of Statistics* (1986). Magnello (1996, 1998, 1999, 2002) explained that whereas Pearson’s main focus was goodness of fit testing, Galton’s emphasis was correlation; Pearson’s higher level of mathematics for doing statistics was more mathe-
matically complex than Galton’s; Pearson was interested in very large data sets (more than 1,000), whereas Galton was more concerned with smaller data sets of around 100 (owing to the explanatory power of percentages); and Pearson undertook long-term projects over several years, while Galton wanted faster results. Moreover, Galton thought all data had to conform to the normal distribution, whereas Pearson emphasised that empirical distributions could take on any number of shapes.

Given the pluralistic nature of Pearson’s scientific work and the complexity of his many statistical innovations twinned with his multifaceted persona, Pearson will no doubt continue to be of interest for many future scholars. Pearson’s legacy of establishing the foundations of contemporary mathematical statistics helped to create the modern world view, for his statistical methodology not only transformed our vision of nature but also gave scientists a set of quantitative tools to conduct research, accompanied with a universal scientific language that standardized scientific writing in the twentieth century. His work went on to provide the foundations for such statisticians as R. A. Fisher, who went on to make further advancements in the modern theory of mathematical statistics.

PEASANT MOVEMENTS

SEE Peasantry.
PEASANTRY
Peasantry refers to peoples and communities who are peasants. The modern English term peasant comes from French and Latin terms referring to residents of an administrative district. In modern times the term has come to refer primarily to small-scale agriculturalists who live in villages and small towns in rural areas. Peasant communities are typically based economically on the cultivation of grains and other high yielding plant foods. Wheat, barley, and oats were first domesticated in the area where Syria, Palestine, and adjacent areas of Northern Iraq are now located and the first peasants appeared in Ancient Mesopotamia (present day Iraq).

The basis of peasant agriculture began with varieties of rice and wheat in Asia, corn and beans in what is now Southern Mexico, and potatoes in the Central Andes (Peru). The grains of Mesopotamia spread into Europe; rice spread into other areas of Asia; the cultivation of corn and beans spread north and south from their centers of origin; and potatoes and some grains domesticated in the Central Andes spread throughout the Andean region. These areas became the bases for the growth of peasantries. Peasants typically produce their crops with simple technology in which the work is done by human labor and the use of farm animals. Unlike farmers who usually employ some hired labor to cultivate large crops primarily for sale in markets, peasants are typically small-scale producers who consume much of each crop that they produce.

The rise of the first civilizations and the economies of most urban areas throughout history were primarily dependent on three ways on rural peasantries. The first way was for food. Due mainly to market systems and taxation, surplus peasant production was typically transferred from rural production areas to towns and cities where food was consumed by non-peasants. The second way in which urban areas were dependent on peasants was demographic. Prior to the development of modern public health practices in the nineteenth century, more people tended to die in cities than were born in them. Throughout history peasants have tended to have relatively high death rates, but have offset their death rate by an even higher birth rate. But due mainly to the inability of peasant communities to economically support growing populations, some percentage of every generation typically migrated to cities and maintained urban populations or caused them to grow. The third form of urban dependency on peasants was for labor. When peasants migrated into cities, they usually occupied the lowest rungs of the social order and provided much of the cities’ manual labor and menial services.

CLASS AND CLASS RELATIONS
An essential component in the sociology, economics, and politics of peasants is the way in which they are positioned in relation to non-peasants. In terms of social class relations, peasants tend to be at or near the lower end of socioeconomic hierarchies and related to non-peasants by forms of uneven exchange whereby they render up more economic value to non-peasants than they receive in exchange. One of the basic features that make possible such uneven exchange between peasants and non-peasants is land tenure. The political importance of land tenure to peasants is expressed in the slogan of the Mexican Revolution, “Tierra y Libertad,” which signals that access to land (tierra) takes precedence over liberty (libertad).

Because they make their living as small-scale cultivators, peasants must have access to land on which to grow crops and raise animals. There is wide variation in the legal, political, and economic aspects of land tenure. The concept of private property, in which land can be bought and sold in a real estate market, is a modern concept. Throughout history it has been common for peasants to live on and work land that is controlled by non-peasants and to whom the peasants are politically subordinate. In non-capitalist state societies the land is typically controlled by a central government that levies taxes on its rural communities. In many other societies, peasant lands are controlled by landlords who charge rent.

State governments also extract surplus from peasants in a number of ways. One of the most common ways is taxation on the crops that the peasants produce or on the land that they use. But taxation of peasants also takes other forms. For example, the monumental architecture of ancient societies, such as the great pyramids of Egypt and Mexico, were built mainly by peasants who had to work on them, typically without pay or other compensation. In feudal societies, peasants may have labor obligations to their lords, whereby they are required to work so many days each year on their farmland or render other services to their landlords. Sharecropping is another form of rent, whereby peasants are given access to land controlled by a landlord, who then receives some fraction of each crop that the peasants working that land produce. In economies with well-developed markets, the peasants may sell part of their harvests to raise money to pay their rents or taxes. In some societies, peasants are required to work lands of the government and also possibly render other services. Also, until recently, peasant conscripts were required to do military service in the armies of kingdoms and states, and of feudal lords. Indeed, until modern times, most of the rank and file members of armies have been of peasant origin.

POLITICS AND THE FUTURE OF PEASANTRIES
Peasants periodically rise up against the lords and governments that impose taxes and rent and other forms of
uneven economic exchange on them. However, the potential for peasant rebellions and political organizing in general is often weakened by internal competition and distrust, which is a result of struggle for scarce resources within peasant communities. Indeed, it was these characteristics that moved German revolutionary Karl Marx (1818–1883) to refer to peasants as like “potatoes in a sack” ([1852] 1972) implying that they were too individualistically oriented to organize as revolutionaries.

But peasantries have on a number of occasions been involved in large-scale regional and national rebellions and revolutions. For example, from 1524 to 1526 German peasants in Franconia, Swabia, and Thuringia joined with impoverished town dwellers (many of whom were no doubt of peasant origin) to mount the “Peasant War,” to redress exploitive relations with non-peasants. This movement was largely unsuccessful, but peasants have been major actors in other major conflicts that have had varied outcomes in the twentieth century, such as the Mexican and Russian Revolutions, the formation of contemporary China, and the Vietnam War of independence against France and the United States.

Until the mid-twentieth century, most of the world’s population could be characterized as peasant, but since that time peasant communities have tended to become more complex, due largely to ever increasing rates of permanent and circular migration from agricultural communities to urban areas. It became common for many formerly-peasant households to be largely dependent on seasonal migration of some of their members who seek salaried work or self-employment. Much of this migration is across national borders, typically from areas and nations of lesser to higher levels of economic development. Such high rates of migration have increased social, economic, and cultural complexity in formerly peasant communities.

PEDAGOGY

At the present time, more is known about how people learn than ever before in human history, and breakthroughs in research are occurring with increasing frequency. The social sciences have contributed enormously to this body of theoretical knowledge, but the diffusion of pedagogical innovations remains problematic. New theories and practices usually do not completely displace existing pedagogies but are simply added to teachers’ instructional repertoire. Moreover, the translation of theory into classroom practice depends heavily on how well individual teachers understand the theories they were taught and how they put them into practice.

During the twentieth century psychologists and educational theorists developed a wide variety of models to explain how humans learn, and it is clear that ongoing basic research has begun to have an impact on pedagogical practice at all levels of the educational system. Recent research in neuroscience has also added a biological dimension to our understanding of the learning process, although the pedagogical implications of this research are still not clear.

Several important themes have emerged from this body of research. For example, there is substantial agreement that in order for deep learning to occur, learners must construct new knowledge themselves, through experience, reflection, and integration. Learners also must build on what they already know and believe, so they must reconcile existing knowledge with new knowledge and correct mistaken beliefs. Metacognitive skills, such as critical thinking and problem solving, are primary goals of learning, but mastery of factual knowledge is also essential to critical thinking. Factual knowledge is best learned within conceptual frameworks that organize it in meaningful ways, and since subject disciplines use different frameworks, students need to learn a variety of approaches for organizing their knowledge.

These theories suggest that students must engage in learning tasks that require inquiry, experimentation, and active engagement in real-world problem solving. Group-based activities and projects are commonly used teaching methods in this paradigm, since cooperation and collaboration seem to facilitate the desired outcomes. The teacher’s content expertise is still important, but it is used in novel ways. Questioning and dialogue largely replace...
lecturing, and the teacher becomes an instructional coach who designs learning activities, facilitates discussion, and guides students through the process of learning.

With various adaptations, these principles can be applied at all levels of instruction, from early childhood to adult education. For example, in an elementary school, students use models of the sun, the earth, and the moon, and a bright lamp to conduct an experiment to explain the phases of the moon. At the end of the exercise, they write up their conclusions and take a test on the essential astronomical concepts. In a college biology course, student groups are presented with a case study on stream pollution. They work collaboratively to pool their biological knowledge, pose researchable questions, develop a learning plan that includes readings for the group, conduct an investigation of the questions, and finally produce scientifically defensible solutions. The product of their work is evaluated on the accuracy of their knowledge, the thoroughness of their research, and the quality of their scientific reasoning.

Although empirical research clearly supports the effectiveness of these pedagogical approaches, only the most progressive educational institutions promote and support them as the primary mode of instruction. Typically, selected activities and projects occur only sporadically within the context of traditional didactic instruction. The reasons these theories have not been more pervasive in education are related to some of the fundamental problems of translating theory into practice.

Beyond the difficulties of mastering new instructional methods and techniques, teachers often find it hard to abandon the role of expert didact and the instructional paradigm of drill and practice under which they were taught. Indeed, educational researchers have found that the intuitive beliefs of teachers about learning have a greater impact on their instructional practices than theoretical models derived from research. Outside the academy, parents and school boards often do not understand these new approaches and may resist their incorporation into their schools. In some cases, state education standards and curriculum guides may contradict new pedagogical models suggested by research. Finally, governments and school systems increasingly require standardized end-of-grade tests as part of school accountability, and teachers can find that “teaching to the test” is more important to their career success than considerations of effective pedagogy.

It is not sufficient for social scientists to demonstrate the effectiveness of new teaching methods and techniques, since pedagogical change requires attention to the gamut of social, cultural, and political forces that mitigate the translation of theory into practice.

PEER CLIQUES

Friendships can foster important psychological and social growth. During late childhood and early adolescence, friends start to gather in a loose-knit collection of members called a peer group. Within these larger peer groups are smaller, tightly organized peer cliques. Peer cliques consist of a small group of close friends, about three to ten, whose members typically resemble one another in family background, attitudes, and values (Ennett, Bauman, and Kock 1996). Cliques, by their likes and dislikes and social status, for example, often constitute “the popular” and “unpopular” groups. Cliques provide a context for acquiring new social skills and for experimenting with values and social roles in the absence of parental monitoring.

Cliques formed early in childhood typically consist of same-sex members; they later begin to diversify, with an increase in mixed-gender cliques in middle and later adolescence (Dunphy 1963; Hartup 1996). Dexter Dunphy’s classic study of Australian adolescent cliques suggests that cliques prepare adolescents for the heterosocial world. Cliques vary in size, but remain small enough to allow frequent interaction among members. Researchers have identified different membership positions within a clique, including a member who affiliates exclusively with the group and a liaison who connects with various other cliques (Ennett and Bauman 1994). Organized around activities, ethnicity, or self-selected friendships, cliques appear to remain stable; instead of dissolving as members leave, cliques replace old members with new members who uphold the group norms (Brown and Klute 2003). Paul Zisman and Vernon Wilson found that when cliques were more tightly organized, they are less likely to include multiple ethnic groups (1992). In most peer cliques a group leader (or leaders) emerges to exercise authority over the group and enforce group norms (Adler and Adler 1995; Dunphy 1963).
A peer clique can be a powerful socializing agent. In a seven-year study of peer cliques of middle-class, European American fourth, fifth, and sixth graders, Patricia and Peter Adler found that clique leaders ridiculed and belittled outsiders and low-status group members, and encouraged other members to act in a similar manner (Adler and Adler 1995). Likewise, Jay Macleod’s 1987 observation of late adolescent boys revealed similar teasing and ridicule of outside members. Group norms and socialization become more precarious when they are marked by homogenous aggressiveness and delinquent behaviors (Cairns and Cairns 1994). Research has demonstrated that antisocial behavior is associated with involvement in deviant peer cliques from early to middle adolescence (Stormshak et al. 2005). Young adolescents form groups based on their similarities in terms of deviance and delinquency.

Importantly, not all cliques are negative or socialize children to act aggressively. Some research suggests that cliques can be a significant predictor of adolescents’ psychological well-being (Hansell 1985; Gauze, Bukowski, Aquan-Assee 1996; Ladd, Kochenderfer, and Coleman 1997). According to researchers, friendships and peer acceptance into the larger group can provide social and emotional support and create a sense of connectedness to the group. Thus, social development and well-being, apparent in factors such as decreased loneliness, are enhanced in positive peer relations. According to Jeffery Parker and Steven Asher, children benefit from being accepted by the group (1993).

PEER EFFECTS

Although researchers have studied children’s peer relationships since the 1930s (Ladd 2005), the end of the twentieth century marked a flurry of psychological inquiry into the impact of peers on development and behavior. Traditionally, adults, especially parents, were considered the primary socializers, responsible for assimilating the child into society. However, according to developmentalists like Jean Piaget and Willard Hartup, children grow up in two distinct social worlds characterized by different types of relationships—the world of adults and the world of peers. Adult-child relationships are hierarchical, with power residing largely with the adult, whose greater experience and knowledge are essential for socializing the child as a new member of society. Yet peer relationships are also critical, though organized quite differently. Contemporary peer relationships are between age-mates of roughly equal power, operating at similar developmental levels, both cognitively and physically. The egalitarian nature of peer relationships makes them unique contexts for developing...
skills like negotiation, perspective-taking, cooperation, problem solving, and so on.

Peers can serve as socializers in the absence of adults, as shown in Anna Freud and Sophie Dann’s (1951) studies of peer rearing among children during World War II (1939–1945) and in Stephen Suomi and Harry Harlow’s (e.g., 1972) studies of nonhuman primates. Even when adults are available, however, peer influences are now understood to be significant. Judith Rich Harris has questioned traditional notions of the socialization process, emphasizing the impact of peers and community in her group socialization theory (GST). Using behavioral genetics research that attempts to specify the relative influence of hereditary versus environmental influences, Harris points out that about 40 to 50 percent of one’s personality is attributable to genetics, but only 10 percent or less can be attributed to family and parenting factors, leaving about 40 percent to environmental influences that are unique to each individual. Harris proposes that the peer group is a significant contributor here, challenging us to consider socialization forces beyond the family.

In understanding peer effects, researchers like Wyndol Furman and Philip Robbins (1985) distinguish between the role of dyadic friendships, which fulfill one’s need for intimacy, affection, and reliable alliance, and relations within the peer group, which meet one’s need to belong in a larger social context. Both friendships and peer group acceptance contribute to development across the life span, though their impact may differ. For example, Catherine Bagwell, Andrew Newcomb, and William Bukowski (1998) found that children’s friendships were associated with better attitudes toward family relationships, greater self-esteem, and lower risk for depression more than a decade later in early adulthood. Being accepted by the peer group also predicted later adjustment associated with higher educational aspirations, better school performance, and job success.

At the dyad level, research by Hartup and others has shown that children and adolescents who have friends are more socially competent, report more positive well-being, and exhibit fewer psychosocial problems than children without friends. Having friends seems particularly important in school adjustment, as the presence of friends facilitates initial school entry (Ladd 1990), helps students navigate later academic transitions (e.g., Berndt et al. 1999; McDougall and Hymel 1998), and impacts students’ school engagement and motivation (e.g., Kinderman et al. 1996; Ryan 2000).

The impact of friends can be positive or negative, depending on who those friends are, or rather how they behave. Young people whose friends exhibit antisocial or problem behavior are far more likely to exhibit negative behaviors themselves (e.g., Brendgen et al. 2000). Thomas Dishion and colleagues (1999) have shown that peer “deviancy training” happens subtly, not just through modeling, but through conversational and behavioral rewards (e.g., laughing when peers describe deviant acts they committed). For children who are already at risk for antisocial behavior due to socioeconomic disadvantage or poor family functioning, the likelihood of going down this path appears to be increased by association with deviant friends (e.g., Ary et al. 1999; Fergusson et al. 1999; Kim et al. 1999). In addition, research by Frank Vitaro and colleagues (e.g., 2001) shows that the success of interventions for high-risk youth is enhanced by less association with deviant peers and more association with nondeviant peers who provide alternative role models and support socially acceptable behavior.

In understanding peer effects, it is important to move beyond popular thinking about “peer pressure” as stemming from power based on coercion (e.g., threat of punishment for noncompliance) or rewards (e.g., influencing behavior by controlling rewards). Peer influences can also be indirect, based on referent power (French and Raven 1959), affecting young people’s attitudes and behaviors simply because others admire them and want to be like them or affiliated with them. As Harris suggests, peers do not just “push”; they also “pull.”

Perhaps the strongest evidence for peer effects comes from research on peer rejection. Since the 1930s, studies have compared individuals who experience good peer relations with those who are disliked or rejected by peers. This research shows that peer rejection predicts later maladjustment in academic (e.g., poor achievement, school dropout), externalizing (e.g., aggression, criminality), and internalizing (e.g., loneliness, depression) realms (McDougall et al. 2001). To explain the effects of peer rejection, Jeffrey Parker and Steven Asher (1987; see also Parker et al. 1995) propose that deviant social behaviors (e.g., aggression, social withdrawal) often lead to peer difficulties and peer rejection, which in turn places a child at serious risk for a host of poor adjustment outcomes, not only because of opportunities for peer-deviancy training, but also because of missed positive peer-socialization experiences that promote healthy development.

Peer group rejection has also been linked to both poor achievement and school dropout (see Juvonen and Wentzel 1996; McDougall et al. 2001), although the process begins in the early years of school. When Eric Buhs, Gary Ladd, and Susan Herald (2006) followed children through elementary school, they found that early peer rejection affected later school engagement and, in turn, achievement. Children rejected in kindergarten were more likely to avoid school and participated less in class over time, but the outcome depended on the peer treatment received. Rejected children who were abused by
their peers were more likely to avoid school. Those who were excluded by peers were less likely to participate, which in turn lead to lower achievement. A critical challenge for educators (see CASEL) as well as parents (see Ruben 2002) is to recognize the interface of peer relationships on academic and life success.

BIBLIOGRAPHY

One of the difficulties that studying peer influence has encountered is the question of whether peers actually do influence one another or whether individuals who are similar to one another simply seek each other out. Although there is evidence that young people who engage in deviant behaviors seek out peers who also engage in deviant behaviors, studies that have been able to control for the effects of peer selection have shown that once deviant peers are together in a group, they do incrementally increase one another’s engagement in deviant behavior (e.g., Matsueda and Anderson 1998).

NEGATIVE Peer PRESSURE AND POSITIVE Peer INFLUENCE

When thinking of peer influence, what comes readily to mind for most people is negative peer pressure. For example, parents, teachers, and other adults worry that adolescents will be pressured by their peers to smoke cigarettes, drink alcohol, have sexual intercourse, or engage in risky behaviors. Indeed, peers can and do influence one another to behave in more deviant ways. In several studies, the best predictor of whether an adolescent will engage in antisocial behavior has been found to be whether he or she affiliates with peers who engage in antisocial behavior (see Pratt and Cullen 2000).

On the other hand, peer influence can also be positive. For example, adolescents can study together, encourage each other to join an extracurricular activity, or provide a fun peer context that does not promote using drugs or engaging in risky behaviors. In fact, the premise of peer mentoring programs is that being paired with a well-adjusted peer can be a positive influence on a youth who is at risk for behavioral or psychological problems.

MECHANISMS OF Peer INFLUENCE

Several influential theories have attempted to explain how peers influence one another. Reinforcement theories emphasize that peers exert influence because they control (consciously or not) rewards that are meaningful. Individuals will behave in ways that are likely to maximize their rewards. Therefore, if an individual perceives that engaging in behavior promoted by peers will result in desired outcomes (e.g., acceptance by the group, high status, access to material possessions), he or she will be more influenced by peers.

Psychologist Thomas J. Dishion’s work on deviancy training has led to a better understanding of the mechanisms through which peers reinforce one another’s behavior during social interactions. Adolescent boys were observed with their best friend in a laboratory setting. The interactions were coded for whether one boy provided positive responses (such as laughter) when the other boy talked about deviant behavior. Boys whose interactions

**PEER INFLUENCE**

The study of peer influence has an important place in the social sciences, particularly in social psychology and developmental psychology. In a now classic series of studies conducted in the 1950s, Solomon Asch (1907–1996), a Polish-born American social psychologist, showed groups of eight to ten college students a set of three lines that differed clearly in length and asked them to indicate out loud which of the three lines was the same length as a fourth line. Only one of the group members was an actual experiment participant; the other group members were associates of the experimenter who were trained to respond incorrectly about the length of the line. In scenarios when the other group members provided unanimously incorrect responses, the experiment participants voiced the same opinion as the other group members one-third of the time. When they were later asked why they responded as they did, the experiment participants generally stated that they knew the group members were wrong in their choice of the matching line but said that they did not want to be ridiculed, ostracized, or thought peculiar by the rest of the group if they gave an opinion that went against the majority view. The many variants of Asch’s experiments have been taken as evidence that peers exert considerable influence on the behavior of one another.

were characterized by this process of deviancy training were found to engage in subsequently higher levels of substance use, violence, and delinquency, even controlling for previous levels of problem behaviors (e.g., Dishion et al. 1996). Nondeviant boys typically ignored rather than reinforced deviant talk.

Modeling is another mechanism that has been proposed to explain how peers influence one another in either positive or negative ways. Peer mentoring programs often count on this mechanism as mentors model prosocial behavior in the hope of eliciting prosocial behavior from their mentees. On the other hand, observing others engage in deviant behaviors might lift an adolescent’s own inhibitions against behaving deviantly. For example, if adolescents observe that many of their classmates drink alcohol or skip school, a given adolescent may feel that social barriers against his or her own drinking or skipping school have been lifted. Fads in clothing or music preferences can also be explained through the mechanism of modeling, which can occur not just between individuals but also at the level of entire schools or neighborhoods.

INDIVIDUAL DIFFERENCES IN SUSCEPTIBILITY TO PEER INFLUENCE

Not all individuals are equally susceptible to peer influence. Age is a key factor that relates to individuals’ susceptibility to peer influence. Peer influence begins in the preschool years and increases in importance over time, generally peaking in early adolescence before decreasing as individuals enter later adolescence. Not only does the power of peer influence change with development, the outcomes that peers influence are likely to change as well. For example, peer influence has been found to affect social behavior among children in elementary school, and youth who are strongly oriented against deviant behavior may be able to resist negative peer pressure. Social contexts can also alter the extent to which peers exert influence on one another. For example, in social situations that are unstructured and unsupervised by adults, adolescents are more susceptible to peer influence than they are in more structured and supervised contexts.

To summarize, despite the ability of peers to influence one another in negative ways, peers can also influence one another positively. Mechanisms through which peers influence one another include reinforcement, deviancy training, and modeling. Furthermore, not all individuals are equally susceptible to peer influence. This entry has focused on peer influence during adolescence because it is at this age when individuals are the most susceptible to peer influence; however, as Asch’s pioneering work demonstrated, peer influence persists into adulthood and can lead individuals to act in ways contrary to how they would be expected to behave in the absence of peers.

PEER RELATIONS

RESEARCH

Peer relations research examines the types and quality of social interactions among same-aged peers. Researchers typically focus their investigation on the quality of each individual’s peer interactions within a given social unit.
The particular social unit under investigation can range from a dyadic relationship (e.g., best friendship) to a small group (e.g., clique) to a large peer group. Dyadic relationships are characterized as close, intimate, bidirectional social relationships where the peers choose to interact with one another. In contrast, a peer group is loosely defined as a large set of peers who interact with one another as a matter of opportunity (e.g., all students in fifth grade). Cliques are small groups within a peer group whose membership is typically based on perceived areas of similarity. Cliques include both a network of bidirectional relationships as well as a group identity (e.g., nerds, jocks).

Within a given social unit, researchers have examined a wide variety of dimensions that typically fall within one of three broad categories: social behavior; social support; and liking. Antisocial interactions (e.g., aggression), prosocial interactions (e.g., cooperation), and social connectivity (e.g., withdrawal) are commonly assessed social behaviors. For example, researchers may measure the amount of conflict that occurs within a friendship or how socially isolated a child is within a peer group. In contrast, social support research focuses on the functional attributes of a relationship, such as trust, intimacy, and aid. For example, researchers may examine the degree to which members of a clique provide companionship and advice for one another.

Numerous studies have been devoted to assessing the level of liking within a social unit. In large part, this emphasis is based on evidence that the experience of liking versus disliking significantly impacts social behavior as well as a broad array of functional outcomes ranging from self-esteem to delinquency to use of mental health services. In a cyclical fashion, liking, social support, and social behavior influence one another over time. For example, poor social skills interfere with the formation of social support networks and decrease liking within the peer group that, in turn, decreases opportunities to practice social skills with peers and exacerbates social behavior problems.

Traditionally, four sources of information have been used to study peer relations: (1) observation; (2) self-report, where persons evaluate the state of their own peer relations; (3) other-report, where key, non-peer adults (e.g., parents, teachers, counselors) evaluate the state of another’s peer relations; and (4) peer-report, where peers evaluate the peer relations of members of the same social unit. With observation methods, social interactions of interest (e.g., cooperative play) are observed (in real-time or via taped archives) within a targeted environment (e.g., playground). The observer is an impartial third party who is trained to evaluate the interactions along dimensions of interest (e.g., frequency, duration, quality).

Self- and other-reports are commonly gathered through paper-and-pencil questionnaires with descriptive items (e.g., troublemaking friends) rated along some scale (e.g., five options ranging from Never to Always). In addition to rating scale questionnaires, sociometrics are a common peer-report methodology through which members of a peer group nominate those peers who match specific social descriptors (e.g., fights a lot). The number of peer nominations received for a particular item is totaled for each member and standardized across the nominating group. Thus, a given member’s social functioning is assessed relative to that of the entire peer group (e.g., highly aggressive). Sociometrics have the advantage of increased reliability and validity due to multiple informants as well as increased sensitivity to variations within a specific group context.

A unique feature of sociometrics is the ability to assess peer group structure. By comparing liking and disliking nominations, researchers can distinguish a member’s place within the social structure, including salience within the peer group (i.e., Social Impact = liking + disliking nominations) and degree of acceptance versus rejection across peers (i.e., Social Preference = liking – disliking nominations). Further John Coie and his colleagues’ (1982) sociometric algorithms identify distinct social status groups: (1) Average = some liking and disliking nominations, but no extreme level of either; (2) Popular = many liking and few disliking nominations; (3) Controversial = many liking and disliking nominations; (4) Neglected = few liking or disliking nominations; and (5) Rejected = few liking and many disliking nominations. Social status is highly predictive of patterns of adjustment over time. In particular, rejection is a significant risk factor for maladjustment across social, emotional, and behavioral areas of functioning.

Development, gender, and group-level factors also need to be considered in the study of peer relations. Peers provide different social functions at different stages of life. Males and females have different social needs and interaction styles. Reputational biases within the peer group can also serve to exacerbate particular social patterns.

BIBLIOGRAPHY

The early ICP comparisons developed a framework and methods but covered relatively few countries. Because there was a strong interest both in wider coverage and estimates over longer periods, the group at Penn, led by Irving Kravis, began to experiment with reduced information methods to extend the estimates to nonbenchmark countries. Robert Summers and Sultan Ahmad developed an early short-cut method to move to more countries, and in 1978 Kravis, Summers, and Alan Heston elaborated the method and published estimates for 100 countries (referring to 1970). The basic method applied the relationship between per capita income and prices for benchmark countries to estimate PPPs of nonbenchmark countries. Summers and Heston took this effort still further, developing estimates for benchmark and nonbenchmark countries that extended forward and backward in time. By the early 1980s the original relationship among the PPP, exchange rate, and per capita income became much less reliable as countries moved to free up exchange rates. In response, Summers and Heston developed an estimating equation based on alternative price sources (e.g., post-adjustment allowances) and per capita income that improved estimates of nonbenchmark countries.

PWT version 6.2 covers 178 countries for some or all the years from 1950 to 2004, with 2000 used as the base year. All of the expenditure estimates are expressed in international dollars, which have the purchasing power over GDP of the U.S. dollar.

The level of detail in PWT includes consumption, investment, government, and the net foreign balance. Estimates are provided in current and constant prices, with both chain, Laspeyres, and terms-of-trade-adjusted GDP series. Per capita, per worker, and per equivalent adult comparisons are provided, along with comparative price levels for GDP and the major components. In PWT 5.6, estimates of the physical capital stock were provided, and this will be resumed in 2007 using an improved methodology.

PWT is widely used as both a research and a teaching resource in development and econometric courses. However, the OECD provides PPP estimates that are more reliable for their member countries than PWT. The main advantage of PWT is that it covers a wider range of countries for a longer time period. The World Bank also provides PPP estimates each year in their World Development Report, but it is only at the GDP level and is not a time series. In PWT, quality grades are provided depending on the number of benchmark comparisons in which a country has participated, and on the consistency of their estimates over previous versions of PWT.

The wide use of PWT reflects the fact that the use of PPPs for the conversion of national currency expenditures to a common currency has proved a more reliable explana-
tory variable in many applications than the alternative converter, the exchange rate. Over time it has been used in a number of cases—such as the appreciation of the Japanese yen and the more recent appreciation of the Euro against the U.S. dollar—when there have been no underlying changes in PPPs or real income levels. The implication is that conversions at exchange rates would have greatly overstated changes in the GDP levels in Japan and the Euro countries relative to the United States. Thus, while PPP conversions were first thought to be an improvement because they better captured differences in real product across countries, it turns out that they are also more desirable for changes over time.

Another advantage of PPP conversions is that they take account of differences in relative prices across countries. The importance of this frequently shows up in comparisons of shares of expenditures in national currencies. There is a systematic tendency for the national currency share of investment of GDP to be overstated for low-income countries and understated for more affluent countries, compared to comparisons at international prices where relative prices of investment to GDP have been taken into account. One consequence is that it appears that low-income countries get less additional output from their investment at exchange rates compared to PPPs.

Similarly, energy consumption in physical units like BTUs, as a ratio to GDP from PWT, provides a much more acceptable measure of energy efficiency than if exchange-rate-converted GDPs are used. This has important implications for the projection of energy consumption and fossil fuel emissions for fast-growing low income countries like China and India. PWT has also been widely used in growth studies testing the hypothesis that per capita incomes of countries will converge over time.

Researchers have used PPP-converted GDP from PWT measures of both production and welfare, but it is an imperfect measure of both. As an indicator of well-being, it is but one important element, and researchers look to other variables as well, such as climate, crime rates, and air and water quality. The United Nations uses literacy and health measures in addition to per capita GDP for its Human Development Index of the Human Development Report of the United Nations Development Programme. Productivity comparisons based on PWT can only be carried out at the GDP level, whereas much greater interest attaches to productivity in sectors of production like manufacturing, retail and wholesale trade, or agriculture. The Groningen Growth and Development Centre (GGDC) has carried out such PPP-based productivity comparisons by sector for a significant number of countries, and in PWT 7.0 (for 2008 or 2009) there will be an attempt to integrate their estimates on a consistent basis with the PWT aggregates.

PWT 7.0 will also undergo a major revision as it integrates the 2005 ICP benchmark comparison. It will provide more expenditure detail, such as actual household consumption, including government-provided health and education expenditures. Alternative methods of aggregation will also be explored, and there will be a more detailed treatment of the net foreign balance, so as to distinguish between production and income of a country. This version of PWT will involve collaboration between other centers, including GGDC and the International Data Center at the University of California at Davis.

PERCEPTION, PERSON
Person perception has been variously assigned such labels as social perception, interpersonal perception, social inference, person cognition, and ordinary personology (Bruner and Tagiuri 1954; Gilbert 1998). Person perception refers to how people perceive and make inferences about other people. Perception differs from sensation in that sensation is the feeling that results from sensory receptors, whereas perception is the interpretation of what is sensed. Person perception also differs from object perception or nonsocial perception because human beings are not invariant and inanimate objects. As targets of our perception, peo-
ple are dynamic entities endowed with emotions, motives, and complexity (Heider 1958).

Person perception is influenced by the characteristics of (1) the perceiver, (2) the situation, and (3) the target person (Jones 1990). Research on perceiver characteristics shows that perceivers are not objective observers of their social world but are active agents whose cognitive and motivational biases color their interpretations of others. Knowledge structures, such as schemas, scripts, or stereotypes, assist perceivers in processing information efficiently. Overreliance on these cognitive structures, however, may create bias and lead to errors in person perception. With knowledge structures providing convenient summary expectations and beliefs about others, perceivers may reach hasty and incorrect judgments, or they may ignore information that disconfirms their expectations (Snyder and Swann 1978). Perceivers do not search thoroughly for information to form impressions of others (Gilbert 1998). Moreover, expectations about a target person can lead perceivers to engender behaviors from the target that confirm perceivers’ initial expectation (i.e., self-fulfilling prophecy) (Rosenthal and Jacobson 1968). In addition, a perceiver may be motivated to form judgments of others that protect the perceiver’s sense of self-worth (Klein and Kunda 1993).

Characteristics of the situation are often overlooked by perceivers when they form judgments of target persons. Perceivers have a tendency to underestimate the importance of situational influence and to overestimate the importance of dispositional factors when they interpret the actions of other people. This tendency is called the fundamental attribution error or correspondence bias (Ross 1977; Gilbert 1998). Perceivers also tend to see that their own failure is caused by external circumstances, while their own success is internally caused. But they are less likely to show this bias when interpreting the success or failure of others, a phenomenon known as the self-serving bias. Person perception research has also focused on the dynamic interpersonal perception between a perceiver and a target person (Kenny 1994) and the cultural influences on these interpersonal processes (Markus and Kitayama 1991).

Certain target-person traits (e.g., the central traits of warm and cold) have more impact than other traits (e.g., the peripheral traits of polite and blunt) on perceivers’ impressions of others (Asch 1946). Negative information also tends to be more heavily weighted in person perception because of information diagnosticity (Skowronski and Carlston 1989). Research has shown that perceivers have implicit personality theories about others, such that an inferential relationship is assumed by perceivers to exist, regarding which target traits seem to co-occur to form a coherent whole (Schneider 1973).

Inferences in impression formation occur not only intentionally but also unintentionally (Anderson and Glassman 1996; Bargh 1997; Uleman 1999). Person perception includes nonverbal communication as well as cognitive inference processes (attribution or social cognition). Representative nonverbal cues are facial expression, voice tone, gaze, interpersonal spacing, touch, and gesture (DePaulo and Freidman 1998). Current work on person perception is also aimed at exploring the implicit associations perceivers have between traits and stereotyped groups.

PERFORMANCE
Performance, as understood in the context of the social sciences, is a process by which individuals (actors) display for others (the audience) the meaning of their social situation. During the last decades, the term performance, which originates from the theatrical context, has become extremely prevalent in various fields and disciplines such as art, literature, and the social sciences. In the United States it has even developed into a specific field of scholarly work, with departments specializing in performance studies. However, performance remains a highly contested concept, one that raises disagreements and divides among scholars.

HISTORICAL DEVELOPMENT
The idea that all social behavior is at least partially a performance is hardly new. It has been with us since the time of the ancient Greeks and the Greek theater, reemerging as a central motif during the Renaissance and the Baroque periods. One of the most famous speeches in William Shakespeare’s play As You Like It reflects this understanding, opening with the words:

All the world’s a stage,
And all the men and women merely players;
They have their exits and their entrances,
And one man in his time plays many parts.

This insightful metaphor was developed into an academic subject of study during the second half of the twentieth century, mainly by the fields of anthropology and sociology. The subject of “cultural performance” (a term coined in 1959 by Milton Singer) became a matter of increased interest among anthropologists during the 1960s. Victor Turner stands out as the anthropologist who probably made the most important contribution to the convergence of culture and theater, with his concept of social drama. This concept, based on the early-twentieth-century work of anthropologist Arnold Van Gennep, expanded the use of drama as a metaphor for nonteatrical cultural manifestations. Working closely with Turner, Richard Schechter, who came from a theatrical background, called for an infusion of theater theory with the work of the social sciences and suggested that traditional drama tends to echo the stages of social drama. Other prominent anthropological contributions to the field were made by Clifford Geertz, who suggested a distinction between “deep play” and “shallow play” in performance; and by Dwight Conquergood, who represents a shift from the anthropological preoccupation with the performer and the performative act to a greater consideration of the audience, the reporter, and the social and political implications of the performance.

ERVIN GOFFMAN AND DRAMATURGY
Sociological interest in the application of theatrical concepts to social life emerged in the second half of the twentieth century. While not the first to write on the theatrical aspects of everyday life (Nikolas Evreinoff, for example, published in 1927 a book named The Theatre in Life, and Kenneth Burke has also importantly written on the subject), it is the work of sociologist Erving Goffman that has really paved the way for the study of social performance. In his seminal and still highly influential book The Presentation of Self in Everyday Life (written in 1956 and reprinted in 1959), Goffman expands many of the ideas discussed by his predecessors. He organizes these ideas into a coherent and well-written dramaturgical analysis of social life in its entirety as a theatrical performance. In this view, we are all actors, playing a role on changing stages in front of various others, who themselves serve simultaneously as our audience and as actors who play a role, to which we are audience. Goffman takes the metaphor of the theater even further. He claims that, as in the theater, social life is guided by scripts and is divided into “front-
stage,” where one performs in the presence of others, and “back-stage,” where the individual practices his act.

This presentation of things begs a subsequent question: Why are we all acting instead of just “being ourselves”? To this Goffman offers a clear answer: It is in our interest to perform in a way that guarantees that others will assess us favorably. In other words, we are constantly working on what Goffman calls impression management, in which we seek to influence the collective definition of the situation by convincing others to accept a positive impression of ourselves. Furthermore, according to Goffman, the self (or rather selves) is shaped and constructed through interactions with others and the various roles one plays in these interactions.

While the dramaturgical perspective seems to convey the idea that people are constantly seeking to deceive others, Goffman does not hold such a position. Rather, he believes that there is nothing inherently fake or inauthentic about the roles we play. In fact, in his view these roles are often part of who we really are. Moreover, the acting itself is not always conscious. People convey impressions both knowingly and unknowingly, and the fact they are always acting does not mean that they are always aware of their act (in fact, all too often they are not). Since there is a mutual dependency between actors and audiences, it is the goal of both sides to protect the performance and maintain its integrity, not to expose its failure.

In later writings (mainly in his 1974 book, Frame Analysis) Goffman expands his analysis, introducing the concept of frames—principles by which the social world is organized, which constrain and limit the possible range of performances and definitions of the situation. By this Goffman expresses the understanding that people cannot simply choose whatever performance they wish and fashion it according to their whim, but are rather constrained by the social context and their position in the social world.

RECENT DEVELOPMENTS
The writings of Turner and Goffman still offer the foundations of performance studies in the social sciences. But other scholars have suggested criticisms and extensions to their pioneering analyses. Most notably, Turner and Goffman were both criticized for focusing on the point of view of the actor and neglecting that of the audience (a challenge that was partially met by the work of Dwight Conquergood and of semiotic perspectives, most notably those of Umberto Eco). Goffman was also criticized for not expanding his theory enough to macrosociological domains and to the mass media. Scholarly work has since attempted to confront some of these challenges and expand the usage of performance ideas in the social sciences. (For example, Jeffery Alexander in a 2006 co-edited volume, Social Performance, offers an innovative cultural analysis of social performance.)

Turning to other disciplines, the contribution of Judith Butler emerges as an original break from former work of Goffman and other sociologists. In her well-known book Gender Trouble (1990) and in subsequent writings, Butler, who takes Goffman as her point of departure, uses the ideas of performance to explore the issues of gender and sexuality. Rejecting naturalistic notions of inherent sexual or gendered essences, Butler argues that the distinctions between homosexual and heterosexual and those between female and male are no more than social constructions. Since they are not based on a real essence, these distinctions are always at risk of disruption and subversion and must be maintained through recurring sexual and gender performances. In other words, rather than simply being a girl or a boy, people constantly act these parts and maintain the distinctions through repetitive performances. Unlike Goffman, Butler emphasizes the discursive parts of performance rather than the actions of individuals. For her there is no self or ontological body, which precede the performance. Thus, in her analysis she uses the term performativity, rather than performance.

The ideas of social performance were also stretched to the study of racial identities and constructions (Majors and Billson 1992), to the study of organizational and political behavior, and to other fields. Many of these accounts reveal an important aspect of social performance—through performance, previously silenced individuals and groups may receive a voice and become visible. As the study of performance continues to evolve, such issues will surely remain at the heart of the debate.

PERIOD EFFECTS

Researchers who investigate human development or social trends face the difficulty of disentangling various effects that lead to change. In such analyses, scientists note that change may occur for three reasons. The first type of change involves social and environmental forces related to the passage of time. These changes are termed secular effects; in this context, secular simply refers to the passage of time and does not imply a contrast with religion or a lack of religion. The second type of change is due to age effects, reflecting physiological changes in individuals. The final type of change relates to cohort effects, the macro conditions that birth cohorts experience over the life span. Because of the close interconnection between age, period, and cohort effects, researchers have noted the importance of teasing apart the relative contributions of these effects. Each effect can contribute independently to change, and there may be interactions among the effects that are not predictable from age, period, and cohort effects individually.

Scientists have developed a number of approaches to identifying the varying causes of change. In some research, investigators may ignore one effect (e.g., age), instead focusing only on the other two (e.g., cohort and period). The obvious drawback here is that one cannot always safely assume that the effect being ignored has not influenced the outcome measure. In other cases, the investigators may examine two of the three effects successively, one effect being temporarily ignored. In this approach, one can identify the relative contribution to an outcome measure by noting whether an effect's absence in one of the models changes the adequacy of a prediction of the outcome.

One frequent topic associated with age, period, and cohort effects is the prevalence of suicide. An example of such research that reveals the importance of period effects, differentiated from age and cohort effects, compared suicide rates in Australia, the United States, and Canada. John Snowdon and G. E. Hunt (2002) identified an increase in suicide rates for successive cohorts in the United States and Canada in the mid- and late twentieth century. A change in Australian legislation limiting the availability of sedatives led to a different pattern. The historical change regarding therapeutic drugs, a period effect, is important in understanding suicide rates in the population. When such period effects were taken into account, estimates of suicide rates among certain cohorts were comparable in the three countries.

In much of the research, the cohort identified is the birth cohort. Some research creates different categories within the birth cohort. Studies of suicide are again instructive in this regard. In the United States blacks have traditionally been at relatively lower risk for suicide than some other groups in the United States (e.g., whites). Since the early 1980s, however, the rate of attempted and completed suicide has risen among blacks. Research has revealed a higher rate among younger black cohorts, as compared to older cohorts perhaps, as Sean Joe (2006) suggests, because of changing religiosity and greater acceptance of suicide.

With any complex social dynamic, however, period effects are not sufficient to characterize all aspects of a phenomenon. For example, in assessing alcohol consumption across the life span, researchers have documented that drinking decreases as people get older. Some of this effect is attributable simply to age. At the same time there is also evidence that cohort effects are important because of socialization factors. Finally, period effects emerge as important; relevant factors can include, as Mary Gilhooly (2005) notes, availability of alcohol, changes in drinking age, the extent of discretionary time in which to drink, and price.

Psychological and sociological studies have used age-period-cohort analysis, but other disciplines also consider these effects. For instance, research has revealed a cohort-period interaction in the voting patterns of citizens of countries formerly part of the Soviet Union. The data showed that, with the fall of communism, older voters tended to resist change, voting for candidates from the old regime. Younger voters, in contrast, embraced a more liberal approach in their voting. In this case, the period effect related to the introduction of a new economic system. Age as a factor was important, but only, as Sara Schatz (2002)
shows, as it interacted with different macro experiences of the various birth cohorts.

Ann Crouter and A. E. Pirretti (2006) observe that in this type of research there are inevitable methodological concerns involving validity of data. Most researchers rely on secondary analyses, using existing datasets. As such researchers studying age, period, and cohort effects have to rely on questions that may not be ideally worded for a given project. Furthermore slight changes in wording across time may have notable effects on results. For instance, in studies on happiness by the Gallup organization, respondents answered a question whose three responses included “very happy,” “fairly happy,” and either “not very happy” or “not at all happy.” When the final response was “not at all happy,” respondents chose “fairly happy” more frequently than when the third alternative was “not very happy.” People were more comfortable declaring that they were “not very happy” but more reluctant to assert that they were “not at all happy.” Such dynamics, as Norval Glenn (2005) notes, complicate the long-term study of behaviors in age, period, and cohort research.

PERIODIZATION

Periodization is an intellectual process that seeks to divide a continuous time interval into parts. Periodization is most frequently used in the social sciences and humanities, especially in such disciplines as economics, sociology, history, and literature. There are two ways to proceed when forming a periodization. One is to divide an entire era into smaller periods that share some homogeneity within them. This is the most common procedure in history periodization, but it is also found in economics and other social sciences. The second procedure is to identify cycles in a historical era, then break the era into phases that can be considered a full cycle. This approach is common in economics.

The origin of the idea of periodization is rooted in the old philosophical principle that there are possible quantitative variations in most concepts associated with social phenomena. Such quantitative variations can lead to qualitative changes in some features of social reality that can be used to define different periods. For example, in a particular period, a given society can be composed mainly of peasants and landlords, but it can also have a small number of artisans. The state in such a society could be controlled by landlords, and most laws would favor the ownership of land and the relationships prevailing in rural areas, with low taxes on land and so on. If the number of artisans grows, they can end up seizing state control. Then, all laws and order could change and become biased to support artisanal production. In this example, a quantitative change in the number of artisans in the society led to a qualitative change in the structure of power and institutional order. A simple periodization in this case would be to divide the history of this society into two parts: One covers the period when political power was under the control of landlords; the second covers the period when political power was controlled by artisans.

More rigorously, suppose that social reality is composed of two sets: One is a set of beings and the other is a set of relationships among them. Any being can potentially be measured, so the relationships among them define relations among quantities of the beings involved. These relationships or beings can have threshold values that change their nature. For example, one being can have two measurable dimensions, A and B; so that A = 0 for B ≤ B₁; where B₁ is a specific threshold value. If B > B₁, A can jump so that A = 1. This rupture of behavior clearly creates the possibility for identification of two periods.

In economics, there is an additional notion of periodization that does not necessarily involve qualitative changes. If some economic variable presents a cyclical behavior, such as a cosine function, it is possible to identify a full cycle as a period, and a periodization emerges from such a procedure. In this case, the moment identi-
fied as the beginning of any cycle is totally arbitrary. Often the date identified as the end of a period, even when the beginning is defined, is also arbitrary, as economic variables are not well behaved. Their stochastic nature jeopardizes the simplicity of cycle identification.

The idea of arbitrariness that arises from the discussion of periodization in continuous variables, which are not subject to qualitative changes, can be extended to social phenomena that contain variables subject to discontinuous behavior. Suppose that there is a set of \( n \) variables and \( m \) relationships defining a social reality, so that \( n > 3 \) and \( m > 3 \). If all the variables are subject to noncontinuous variations, any particular variable or combinations of them may be taken as parameters to define ruptures that could characterize change in periods. Therefore, different researchers could take distinct variables or their potential combinations to identify periods, and distinct periodizations would emerge.

In addition to the imprecision resulting from the selection of different criteria for the identification of periods, it is also possible for disputes to emerge concerning the moment in which one criterion exhibits enough change to lead to a period break. Measurement of many social variables is not easy, and most of the time variables have a stochastic component that makes it difficult to identify the moment they actually reached the relevant value that generated the qualitative period change.

Periodization also tends to be historically determined, as each culture and each era has its own set of most relevant social phenomena that normally serve as the basis from which to draw criteria. Such difficulty in establishing a periodization, along with the other problems discussed above, have caused some researchers to condemn the practice of periodizing history.

PERMANENT INCOME HYPOTHESIS

The permanent income hypothesis (PIH), introduced in 1957 by Milton Friedman (1912–2006), is a key concept in the economic analysis of consumer behavior. In essence, it suggests that consumers set consumption as the appropriate proportion of their perceived ability to consume in the long run. Wealth, \( W \), is defined as the present discounted value of current and future total income receipts, inclusive of income from assets. Under the assumption that the household is infinitely lived, permanent income can be defined as that level of income which, when received in perpetuity, has a present discounted value exactly equal to the wealth of the household. Equivalently, permanent income, denoted \( y^p \), may be regarded as the amount it is believed possible to consume while maintaining wealth intact; it is therefore expressed as equal to the “annuity value of wealth,” \( y^p = rw \), where \( r \) is the real interest rate (assumed fixed).

More specifically, the PIH decomposes measured total disposable income, \( y \), into a permanent component, \( y^p \), and a transitory component, \( y^t \). The permanent income component is deemed systematic but unobservable, reflecting factors that determine the household’s wealth, while the transitory component reflects “chance” income fluctuations. Similarly, measured consumption, \( c \), is decomposed into a permanent component, \( c^p \), and a transitory component, \( c^t \). Assuming these relationships to be additive, for simplicity: \( y = y^p + y^t \) and \( c = c^p + c^t \). It is also important to note that the PIH defines consumption in a “use sense,” through the enjoyment or destruction of consumer goods by use, rather than the expenditure upon them, so that consumption is regarded as a service flow.

In giving the hypothesis empirical substance, Friedman assumes the transitory components to be uncorrelated across consumption and income, and with their respective permanent components. The second of these assumptions follows from the definitional decomposition and the nature of transitory components. The first implies that irregular income will not result in unplanned consumption. Friedman defends this assumption by arguing that transitory income changes are likely to be reflected in changes in asset holdings. Further, since the consumption definition includes only the flow of services from goods, transitory income disbursed on durable goods may still be classified as unplanned savings. Moreover, zero correlation implies only that the average association is zero, and positive associations in some instances may well be offset by negative associations in others.

The formal relationship between consumption and income is derived from a standard intertemporal utility-maximizing framework under the assumptions of infinite life, perfect capital markets that permit borrowing and lending of unlimited amounts (subject to solvency) at the same real interest rate, and the condition that the utility function is homogeneous of positive degree in consumption for current and all future periods, such that an expansion in the feasible budget set (arising from increased...
income in any period) leads to an equal proportionate change in present and planned future consumption. As a consequence, at the level of the household, permanent consumption is a proportionate function of permanent income. That factor of proportionality is dependent on tastes, age, and the real interest rate (and, with allowance for uncertainty, on the ratio of financial assets to permanent income, on the basis that financial assets provide more substantial collateral than “human wealth” in the form of discounted unearned future income). The aggregate consumption function then depends on the distribution of these factors across households. If it is further assumed that the distribution of households by income is independent of their distribution by these factors, then aggregate permanent consumption obeys a simple proportionate relationship to aggregate permanent income: \( c^P = q Y^P \).

This proportionate relationship between the permanent components of consumption and income is readily reconciled with the nonproportionate aggregate relationship typically observed empirically in cross-sections and short-run aggregate data studies. This is as a consequence of low-income brackets including a greater proportion of households with negative transitory income, and high-income brackets including a greater proportion of households with positive transitory income. However, without any impact on consumption, which is still proportionate to the permanent income of those households, the observed consumption-income relationship is shallower than the underlying proportionate relationship between the permanent components (see Figure 1). More specifically, for zero mean transitory components and a random transitory income distribution, the cross-section average income group consumes cross-section average permanent income. For the above-average “high” income group, transitory income will typically be positive but not reflected in consumption, though assets will be accumulated. Similarly, below-average “low” income groups are more likely to have experienced negative transitory income, which reduces income below the permanent income level, associated with negative changes in asset holdings. Thus, the asymmetric incidence of transitory income generates an observed consumption-income relationship that is disproportional and lies away from the underlying proportionate behavioral relationship. Note that the exact shape of this observed relationship will depend on the actual distribution of transitory income in practice, while its positioning in the diagram will depend on the true cross-section average transitory income and transitory consumption values, which may not be zero as illustrated.

Over time, as aggregate average permanent income grows

Figure 1: The cross-section representation of the permanent income hypothesis.
along trend, the cross-section consumption function shifts up, tracing out a long-run time series of aggregate average consumption and income that exhibit a constant ratio with respect to each other.

A major difficulty in attempting to test the PIH empirically is that permanent income is not observable. This necessitates the use of some proxy or means of estimating permanent income. In the empirical implementation of the permanent income hypothesis using time-series data, Friedman utilized an adaptive mechanism to relate permanent income to current and past measured income, with the greatest weight attached to current income and declining weights attached to income further in the past. That is, permanent income is represented by an exponentially weighted average of all observed measured incomes, with the weights summing to unity. This approach, with some truncation of the influence of past incomes, enabled Friedman to estimate the weight attached to current income in contributing to permanent income at around one-third (and therefore far less than unity, as would be implied by the absolute income hypothesis) and to demonstrate the long-run proportionality of consumption and income, as implied by the PIH.

It is also of some note that the infinite distributed lag formulation of permanent income may also be expressed equivalently in terms of a finite adaptive expectations representation for permanent income, such that if current measured income exceeds the previous period’s estimate of permanent income, then the estimate of permanent income for the current period is revised upwards, the extent of the adjustment depending on the size of an adjustment parameter in the adaptive expectations mechanism. Algebraically, taking the infinite distributed lag formulation of permanent income, making use of the Koyck transformation and the definition of permanent consumption as the difference between measured and transitory consumption, it is then possible to express current measured consumption as a function of current and past measured income, measured consumption in the previous period, and an error term. However, this time series representation is “observationally equivalent” with the implications of alternative theories of consumption, such as the relative income hypothesis, thus weakening the distinctiveness of the permanent income approach (though it should be noted that this criticism is less damning to tests of the cross-sectional implications of the PIH noted above).

An ensuing criticism of the PIH is centered on the assumption of an adaptive relationship between permanent and measured income, which implies an underlying adaptive expectations mechanism, as discussed above. This criticism hinges on the observation that such expectations are entirely “backward-looking,” in the sense that expectations are only revised in response to past movements in income, and such revisions are in general sluggish, which suggests the possibility of systematic expectation errors. However, it is not a tenable proposition that rational economic agents, who are assumed to be optimizing subject to constraints in all other regards, would not seek to revise their expectation formation mechanism, and the information on which it draws, in such circumstances. The essence of the rational expectations hypothesis (REH) is that agents should utilize all relevant and available information in avoidance of systematic error, and the incorporation of the REH into the PIH therefore has considerable ramifications. Predominant amongst these is the implication that consumption should follow an approximate random walk, such that knowledge of previous values of any variable other than the immediately preceding level of consumption should have no predictive power for consumption, since all information available in the previous period should have been incorporated in determining the previous level of consumption. However, the available empirical evidence is not generally supportive of this proposition in its strict form, and the ensuing debate has reinforced the view that the validity of the results of tests of the PIH depend as much on the method used to represent permanent income, and in particular the relationship between current and expected future income, as on the validity of the PIH itself.

From a policy perspective, the PIH asserts that current income plays only a minor role in consumption determination, as just one element of the entire spectrum of current and expected future income, and emphasizes the assumed desire of consumers to smooth consumption flows in the face of variable income flows. In particular, conventional Keynesian demand-management policy, as might be conducted through countercyclical fiscal policy in the form of temporary income tax changes, will lead to little or no change in consumption and be relatively ineffective, since only changes perceived by households as leading to revisions in their permanent incomes will impact significantly on their consumption. Thus, transitory income movements are largely reflected in saving changes. Moreover, the economic system is consequently inherently more stable in that the income-expenditure multiplier effects of exogenous changes are reduced, so that the change in national income following a temporary change in private investment or government expenditure, for example, is correspondingly much smaller than when consumption is directly responsive to current income alone, as is the case under the Keynesian absolute income hypothesis.

However, a caveat to the preceding policy discussion is warranted in that it must be remembered that the PIH is concerned with consumption as a flow of services, as distinct from the implications for consumer expenditure, which includes expenditure on durable goods, and it is
this latter concept that is important in income-expenditure analysis. Thus, while transitory income movements are reflected in savings and asset changes under the PIH, such assets include durable goods, and the potential for a sizeable multiplier effect to operate is opened through the relationship between current income and durable-good expenditures. Moreover, to the extent that capital markets are imperfect and consumers do not have good short-term lending and borrowing opportunities, the tendency toward holding transitory income in durable goods is strengthened. The issue of countercyclical policy effectiveness then becomes one of determining what form asset accumulation and associated expenditures take, and what factors influence those expenditures.

Perhaps most critically, the PIH embodies the assumption that capital markets are perfect in the sense that lenders are prepared to extend credit on the basis of repayments financed out of future income yet to be received, at a fixed rate of interest irrespective of loan size, and equivalent to the loan rate payable to deposits. However, where consumers are unable to borrow freely on perfect capital markets, possibly as a result of adverse selection and moral hazard under limited and asymmetric information, liquidity, as the ability to finance consumption, and liquidity constraints, involving limitations on the volume of borrowing as well as divergences between rates of interest on borrowing and lending, become paramount. In such circumstances, increases in current income are likely to be used to finance increased consumption, thus accentuating the observed consumption-income relationship, particularly where lenders select current income as the credit rationing device from among the observable characteristics conveying information on ability to repay debt.

PERÓN, EVA
SEE Peronism.

PERON, JUAN
SEE Peronism.

PERONISM

Peronism is the name of the most important political force in contemporary Argentina. It emerged from the first and second presidencies of Juan Domingo Perón, who was democratically elected in 1946 and, after winning elections in 1952, was overthrown by a military coup in 1955. Beyond being a political party, Peronism has been a social and political movement firmly entrenched in the organization and political identity of Argentine society, and has given birth from the 1970s to the 2000s to different political factions with conflicting ideologies and programs.

Perón’s election to the presidency in 1946 represented a reaction to the economic and industrial changes introduced by military regimes following an oligarchic restoration (1930–1939). Peronism emerged as a working- and lower-class movement, and survived an eighteen-year ban on the party, the exile of its leader (1955–1973), decades of repression, and the 1974 death of Perón, then serving his third presidential term.

Even though there is general agreement that the changes implemented by Perón transformed Argentine society, politics, and culture forever, the true character of Peronism has been widely disputed. While it has been presented as one of the paradigmatic cases of Latin American populism (De la Torre 1992), it has also been seen as a political movement with certain affinities with fascism, due to the dictatorial style of Perón’s government and Perón’s open admiration for Benito Mussolini. Peronism has also been studied as a strategic alliance of the working classes with the state (Murmis and Portantiero 1971), among other interpretations.

According to Daniel James (1988), one of the constitutive elements of Peronism was a belief in the essential virtue of the people. Perón considered the organization of labor vital for the success of the state in asserting workers’ rights against the interests of the oligarchy. Peronism was associated with the achievement of higher wages, the generalization of a system of collective bargaining, greater levels of unionization, and better living conditions for the working classes and the poor. Peronism represented an expanded notion of the meaning of citizenship, and challenged the accepted forms of social hierarchy and traditional symbols of authority.

At the same time, Peronism was characterized by nationalism and corporatism, an emphasis on class harmony and the central role of the leader, and the overwhelming presence of a paternalistic state. Industrialization was one of the most important goals of Perón’s government (Rock 1987).

The impact of Peronism on the working classes’ organization was ambiguous, and thus did not have a single meaning for those classes. As James notes, the Peronist state made great efforts between the late 1940s and the
mid-1950s to institutionalize and control the workers’ movement, whose demands Perón had earlier encouraged, and to absorb it into the framework of a new state-sponsored orthodoxy. From this perspective, Peronism can be seen as a demobilizing force encouraging passivity among workers, who were limited in their actions by a powerful and controlling state. However, efforts to control the unions from above did not prevent the emergence of a strong oppositional culture among workers, which was the foundation of “rank-and-file resistance to the post-1955 regimes and became the basis for the reassertion of Peronism as the dominant force within the Argentine workers’ movement” (James 1988, p. 40). As a political movement, Peronism drastically changed the way in which the Argentine working classes behaved politically, and how they related to other groups. Most workers saw in Peronism the promise and possibility of a better society in which they would have a vital role.

More than fifty years after its emergence, Peronism remains linked to the image of Perón, and his second wife, Eva Perón, known as Evita. Although both Perón and Evita were strong, charismatic leaders, Evita played a particularly important role in gaining the devotion and unconditional loyalty of the working classes through her speeches and actions. Her direct distribution of aid to the poor is still remembered among Argentines, and her image serves as a model for many women politicians.

Peronism not only divided Argentine society in two groups—namely, Peronists and anti-Peronists—it also has divided itself into many “Peronisms,” with competing ideological perspectives, including socialist, nationalist, and conservative tendencies. Drawing rhetorically on Peronist ideals, symbols, and myths, and counting on the organizational support of the Peronist party, Carlos Menem—president of Argentina from 1989 to 1999—shaped a neoliberal project that was in fact antithetical to the original Peronism. In contrast, in 2003 Néstor Kirchner became president following a campaign based on the same kind of Peronist themes, but set out to establish a completely different political and social program, probably closer to the original Peronist ideals.

PERRON-FROBENIUS THEOREM

PERSON MEMORY

The term person memory came into common usage around 1980 in conjunction with the advent of the contemporary field of social cognition, with the two labels sometimes used interchangeably. As described by Reid Hastie and colleagues in their 1980 book, person memory is an attempt to “extend accounts of the formation, representation, and retrieval of first impressions of other people” (p. 1) by borrowing extensively from the field of cognitive psychology. From the beginning these extensions have relied heavily on cognitive concepts such as the information processing model, schemas, and associative network models of memory representation and retrieval.

The information processing model distinguishes stages of attention, perception, memory storage, retrieval, and judgment. Prior to 1980 researchers in social psychology had developed an extensive literature on person perception and attribution, which focused primarily on the earliest of these stages, the formation of impressions, without much regard for issues relating to memory representation or retrieval. Consequently, the term person memory came to apply principally to post-1980s work that extended impression formation work to the later stages of information processing.

The earliest research in person memory demonstrated that people’s impressions of others comprise separate trait and episodic representations, and that these affect each other in complex ways. For example, researchers suggested that inferred traits serve to organize behavioral episodic representations, and that this actually facilitates recall for behavioral information. Subsequent research examined the effects of a variety of processing goals on the way that impressions and memories are organized and retrieved from memory.

Other person memory work examined an implication of schema theory, that people ought best to recall behav-
ioral episodes that are congruent with their trait impressions. Person memory researchers actually found the opposite, with recall being best for episodes that contradicted prior trait impressions. Applying associative network models popular in that era, theorists suggested that as perceivers attempt to reconcile incongruent evidence with their trait impressions, they create a rich network of interconnections among these episodic memories, facilitating their ultimate retrieval. Of course, as the amount of incongruent information increases, it becomes more likely that perceivers will eventually abandon their initial trait impression. However, research indicates that first impressions tend to have persisting effects even in the face of substantial contradictory evidence.

Later work in person memory suggested that because of the incongruity effect and other such memory processes, people's memories of their trait impressions will not always correspond exactly with their memories for relevant facts and events. In fact, such correspondence is to be expected primarily when people actually base their trait impression on recalled facts and events, which is most likely when they failed to form an impression as those facts and events were initially encountered. Contemporary research on social cognition continues to examine issues surrounding the way that impressions are represented in memory, with some additional interest in the spontaneity of impression formation and the degree of conscious awareness that people have of their impressions.

**PERSONAL CONSTRUCTS**

According to personal construct psychology, developed by the American psychologist and personality theorist George Alexander Kelly (1905–1967), individuals create personal constructs to organize ongoing experience and anticipate future events. A personal construct is a bipolar mental template, consisting of something and its perceived opposite. For example, one person might develop the personal construct dimension of “safety versus adventure,” in which safety is seen as objectionable and boring. Another person might develop a personal construct of "safety versus terror," in which safety is desirable and soothing. Clearly, these two people mean different things when they report feeling safe. Personal construct psychology contends that in order to organize experience coherently and understandably, each person develops a set of unique personal constructs. One's personal construct system is structured hierarchically, with some constructs more central and influential to how the world is understood than others. Accordingly, people often construe the same circumstances in vastly different ways. This reflects personal construct theory's notion of constructive alternativism, which holds that there are an infinite number of personal constructs available. People often mistakenly believe their manner of construing things is the only correct way, when all situations can be construed in countless ways.

Kelly most fully developed personal construct psychology in a two-volume work, *The Psychology of Personal Constructs*. Originally published in 1955, the volumes present personal construct psychology in a formal manner intended to be least offensive to the professional sensibilities of 1950s psychology. Kelly presented his theory as a fundamental postulate and eleven corollaries. The fundamental postulate states that people organize their psychological experience in ways that help them most effectively anticipate events. Kelly stressed viability over validity in personal construct psychology. Because people only access the world indirectly through their personal constructs, they can never be certain that their constructs match reality; the validity of constructs can never be fully established. However, people can know whether their constructs work adequately and help them to successfully navigate life. Thus, the viability of constructs takes center stage in personal construct psychology.

Kelly's eleven corollaries explain how people's personal construct systems function. For example, the individuality corollary maintains that each individual creates a unique set of personal constructs, while the fragmentation corollary contends that different subsections of one's personal construct system may be contradictory—after all, in different areas of their lives, people are often inconsistent. The choice corollary holds that people choose the poles of constructs that they think will be most likely to help them make productive sense of new situations. Once people choose to apply certain constructs to anticipate a situation, the experience corollary explains how they judge the effectiveness of the constructs they applied. When constructs are not found to be effective, people often revise them. As a final example, the sociality corollary asserts that when two people construe each other's construction processes, they can come to understand one another and form a close relationship—which Kelly referred to as a role relationship.
Clinically, Kelly developed a psychotherapy technique called fixed-role therapy. In fixed-role therapy, the therapist asks the client to adopt a different identity for a two-week period. The client is asked to act the part of someone whose constructions and behaviors are significantly different from the client’s. Because the client is only playing a role, any threat that might occur as a result of violating one’s own personal identity are minimized. After all, the client is simply playing a part. However, in so doing the client experiments with alternative ways of construing and behaving that may produce personal growth.

Personal construct psychology has become associated with theories of constructivism, which emphasize that people know the world indirectly through constructed understandings. Radical constructivism views the person as a closed system, one in which a person’s internal psychological structure determines experiential reality. One’s structure is only sensitive to specific kinds of stimulation from the external world. People do not experience the world as it is, but rather experience it only in the ways their internal structure allows. On the other hand, social constructionism deemphasizes individual knowledge construction and instead stresses that human understandings spring from ongoing relationships. Through discussion and interaction with each other, people negotiate and reach consensus about what is real and true. Discourses, defined as ways of talking about reality, shape human experience. As people use discourses in novel ways over time, shared constructions of reality evolve. Whether individually or socially focused, constructivist theories stress human involvement in knowledge construction, maintaining that people can only know the world indirectly via their constructions.

Jonathan D. Raskin

PERSONALITY

Personality most commonly refers to the psychological features that distinguish one individual from another—regularities in the way an individual thinks, feels, and behaves. Although other characteristics may also distinguish individuals (for example, hair color, nationality, or job title), it is the psychological differences that fall under the umbrella of personality. These differences may be broad in nature, such as whether a person is outgoing or shy, emotional or calm, or they may be narrower in scope, reflecting finer grained patterns of beliefs, attitudes, and behaviors that may emerge only in certain situations. A person’s total collection of these characteristics defines his or her personality.

Personal also refers to a separate subfield of psychology that uses the scientific method to investigate people’s defining characteristics—what the characteristics are, how best to measure them, and the consequences for individuals who embody them. The young field of personality psychology was influenced by several early movements of the nineteenth century, starting with the European and North American philosophical tradition of individualism. Personality psychology emerged most prominently in the 1930s with the publication of the highly influential 1937 textbook Personality: A Psychological Interpretation, written by the psychologist Gordon Allport (1897–1967). The first personality inventory was conceived during World War I to predict who would be more emotionally fit for warfare. Since that time personality psychology has continued to emphasize sound measurement to capture a variety of aspects of human personality.

LEVELS OF PERSONALITY

Given the multitude of psychological differences among people, it is helpful to organize these differences into levels. For example, the psychologist Dan McAdams (b. 1954) has organized personality at three levels.

Traits At the broadest level, individuals differ in what are called dispositional traits. Traits outline the coarsest differences among people and reflect the most general and enduring orientations on the world.

Although different traits have been proposed throughout history, the earliest of which subdivided individuals into groups based on prominent bodily fluids or “humors” like blood (sanguine), yellow bile (choleric), black bile (melancholic), and phlegm (phlegmatic), in the early twenty-first century there appears to be some consensus on a trait taxonomy, commonly referred to as the “big five.” The big five personality traits are: extraversion (social, outgoing, energetic, and able to experience positive emotions), agreeableness (yields to and trusts others), conscientiousness (productive and follows through on
tasks in an organized fashion), neuroticism (high anxiety, emotional instability, and hostility), and openness to experience (willingness to explore and engage in novel ideas, experiences, and feelings). These traits are continuous rather than categorical, with fewer people on the extremes and most people falling in between these extremes. Traits are controversial because they do not always predict how a person will behave or feel in a given situation because situations often constrain behavior. Instead, traits are more like statements about the probability that a person will behave in a certain way. Traits do predict important outcomes over longer periods of time, however. For example, extraversion predicts the time it takes people to develop a network of friends in a new environment. Likewise neuroticism is a risk factor for cardiac problems. Traits also have a strong genetic component, with evidence that about half of the variability in personality traits derive from genetic factors (that is, heritability quotients of 40 to 50 percent for most of the big five traits).

Consensus regarding the big five comes after decades of research, beginning in the 1930s with a painstaking search for terms in The Oxford English Dictionary that could be used to describe individuals. This task, undertaken by the prominent early personality theorists Gordon W. Allport and Henry S. Odbert, was guided by the principle that all of the important ways of characterizing people will be encoded in natural language use. Using this word list as a starting point, personality researchers like James Cattell and Hans Eysenck reduced the list into a smaller and more manageable number of categories using statistical techniques like factor analysis. In analysis after analysis, five personality dimensions consistently emerged, which came to be known as the big five. Other taxonomies have been proposed, for example, Eysenck focused on the big three, extraversion, neuroticism, and psychoticism (a combination of agreeableness and conscientiousness). Since the big five was developed, taxonomic analyses have yielded fairly good cross-cultural consistency in the five dimensions.

Other popularly known personality traits include type A and type B personalities. Type A individuals are typically driven, impatient, competitive, aggressive, and hostile, whereas type B individuals are the opposite—they are relaxed, patient, noncompetitive, and less hostile. The A/B distinction originated in the 1950s with a team of cardiologists who observed fast-paced aggressive behaviors in patients with coronary heart disease. Studies have subsequently confirmed type A as a cardiovascular risk factor—an association that appears driven by the hostility component and its negative physiological effects on blood pressure. Perhaps because of its intuitive appeal, “type A personality” moved into popular jargon fairly quickly. Fortunately the popular understanding of type A appears fairly true to the original concept.

Other related personalities include the controversial type C or “cancer prone” personality, which is characterized by emotion suppression. The associated type C coping style is characterized by denial of distress in spite of physiological evidence of distress. Evidence linking these characteristics to the incidence and recovery from cancer is mixed, however. Lastly, there is type D or distressed personality, characterized by negative emotionality, an inability to express emotions, and social isolation, which has been linked to greater cardiovascular disease and increased mortality.

Characteristics Adaptations At the next level of personality differences are mid-level characteristic adaptations, which comprise nuanced differences among people. Unlike traits, many of these adaptations are learned through experience, are readily influenced by culture, and reflect a dynamic interplay between people’s current contexts and situations. It is at this level that conditional theories of personality emerge as alternatives to trait theory.

One of the issues with defining personality solely as traits is that traits lead us to expect people will behave in a regular way across all situations. Yet empirical data do not show this. Typically the correlation between traits (as measured by standard trait questionnaires) and behaviors measured across situations is relatively modest—with correlations of .30. This observation, made by the personality psychologist Walter Mischel (b. 1930) in his influential 1968 text Personality and Assessment, sparked a decades-long debate in personality known as the person-situation debate. This debate threatened the field of personality because it undermined the influence of personality traits on behavior and elevated the influence of situations on behavior, a perspective favored by social psychologists. One consequence of the debate is that it stimulated a more contextualized and conditional approach to personality, exemplified in Mischel’s research with his colleague, the psychologist Yuichi Shoda. From their perspective, personality emerges as situation-specific behavioral signatures—regularities in behavior that manifest in certain situations, not in all situations. Thus two people who are similar at the trait level (for example, high in neuroticism) may manifest different behavioral signatures. One person may react with hostility when confronted by authority, and another may react that way when confronted by a subordinate.

Central to a conditional approach to personality are people’s interpretations or construals of their immediate environments. This theme derives from a social-cognitive perspective on personality, which emphasizes the operation of acquired beliefs and expectations about the world in personality functioning. Within this social-cognitive perspective, there are several other types of individual dif-
ferences that contribute to people’s behavioral signatures. Of particular importance are people’s beliefs regarding their self-efficacy, whether they believe they are capable of achieving desired outcomes through their actions. Formalized in theory by the psychologist Albert Bandura (b. 1925), self-efficacy beliefs are shaped from people’s experiences in the world and influence motivation, expectations, and the explanations people give for their outcomes. Self-efficacy and other human strengths, such as optimism, wisdom, and empathy, have received increased focus among personality and social psychologists. Also important are our implicit theories about the rigidity versus mutability of self-attributes. Some individuals, referred to as “entity theorists,” view their attributes, such as intelligence, as fixed and unchangeable, whereas others, “incremental theorists,” view their attributes as more malleable and able to be cultivated. These personal theories, which are heavily influenced by parenting, set up characteristic styles for how people approach and respond to challenging tasks, with incremental theorists being more likely to persist at tasks requiring effort.

Mid-level differences also include motives and drives. Within each culture, individuals differ in several higher-order motives—whether they are driven to achieve, affiliate with others, or have power over them. At the individual level, a person may also have his or her set of personal strivings—the idiosyncratic ways in which an individual tries to implement his or her goals in everyday life. For example, a person with strong affiliation motives might regularly get together with friends. A person with strong achievement motives might work long nights to achieve professional goals. Individuals may not always be aware of what motivates them. “Unconscious motives” are quite common and occur when a person regularly exhibits behaviors consistent with a motive but is unaware of having this motive. In these circumstances an external observer can often see these patterns more clearly than can the person.

Other mid-level aspects of personality, not just motives, can operate at an unconscious level. It is known that individuals possess considerable knowledge about themselves and their past experiences that they cannot verbalize or represent in consciousness but that shapes their feelings and behaviors. Such knowledge is often associative in nature and measured indirectly in ways that bypass self-report (for example, using computerized tasks adapted from cognitive psychology). This knowledge may be different from other reflective forms of self-knowledge that people can verbalize and report using questionnaires. Understanding the functions and interplay between associative and reflective components of personality appears to be among the major tasks of twenty-first-century science in personality. Another example of unconscious personality processes is found in defense mechanisms, which reflect patterns of thinking that minimize conscious awareness of threatening thoughts or feelings. With repeated and frequent use, defense mechanisms can become part of a person’s characteristic style of thinking.

**Personal Narratives** In addition to traits and characteristic adaptations, individuals differ in their integrative life narratives. Life narratives are the unique person-specific stories people create about their experiences to provide coherence and meaning to their lives. A life story encompasses who a person is, how this person came to be, and what the future holds. Although each story is unique, common themes do emerge—despair, resurrection, and triumph—that are often culturally bound. Narratives also have important psychological consequences, as evidence suggests that writing about a traumatic experience in a way that gives the experience coherence and meaning speeds recovery and improves mental and physical health.

**PERSONALITY DEVELOPMENT AND CHANGE**

Change depends on whether personality is conceived of as traits, characteristic adaptations, or life narratives. Traits exhibit the most stability and are the hardest to change, which is consistent with traits being partly heritable and rooted in infant temperament. Early learning environments can play some role in shaping the expression of traits, however. For example, temperamentally introverted children who are exposed to intensive social environments early in life, such as day care, evidence less introversion later in life, but they may never be as outgoing as children who exhibited extravedted behaviors prior to socialization.

Traits crystallize between ages twenty-one to thirty, after which they show consistency through older adulthood. Of course people are dynamic, and they can change across their lifetime. Such changes, however, appear to occur at the level of characteristic adaptations and life narratives. Indeed therapy is often targeted at changing people’s beliefs, motivations, coping strategies, and life stories rather than changing enduring dispositions. Personality also changes through adult maturational stages characterized by decreasing impulsivity, maturing defenses, changing identities (for example, parenthood), and a shift in orientation from self to other.

**BIOLOGICAL SUBSTRATES OF PERSONALITY**

Personality psychologists have begun to understand the neurobiological underpinnings of traits such as extraversion and neuroticism. For example, extraversion and its associated qualities of impulsivity and sensation seeking appear most strongly linked to the behavioral activation system (BAS), which consists of dopamine-transmitting pathways in the brain and neural structures that modulate
the extent to which people feel pleasure in response to cues for reward. By contrast, neuroticism appears most strongly linked to the behavioral inhibition system (BIS), a set of neural structures and processes involved in anxiety and the processing of aversive outcomes such as punishment.

New avenues of research in molecular genetics hold promise for investigating links between genes and personality. For example, emergent research suggests that variation in a gene related to dopamine function (DRD4) is associated with personality differences in novelty seeking, just as variation in a gene related to serotonin function (5-HT transporter) has been linked to differences in neuroticism. The mechanisms of action between genes and personality are complex and not yet known, however. Research in genetics will likely yield important advancements in the years to come, particularly with respect to multiple gene contributions to personality, mechanisms of action, and gene-environment interplay.

DISORDERED PERSONALITY

Personality disorders appear to represent the extremes of normal variation in broad personality traits. Many of the personality disorders described in the 2000 Diagnostic and Statistical Manual of Mental Disorders, fourth edition text revision (DSM-IV-TR), correspond to extreme variants of the big five personality factors. For example, borderline personality disorder—characterized by impulsivity, self-destructive behavior, and emotional instability—may be a maladaptive form of the anger and hostility subfacets of neuroticism; obsessive-compulsive disorder may be related to extreme conscientiousness, with an extreme focus on order, perfectionism, rules, and structure; and paranoid personality disorder may be related to extremely low agreeableness, reflecting a wariness and mistrust of others.

PERSONALITY, AUTHORITARIAN

The rise of fascist ideology and virulent anti-Semitism in Europe during the 1930s posed important questions for social scientists. Psychologists suggested explanations that drew on both psychoanalysis and Marxism. Wilhelm Reich (1897–1957) proposed that capitalism and sexual repression produced sadomasochistic personalities blending aggression toward the weak and vulnerable with deferential submission to power and authority. Abraham Maslow (1908–1970) and Erich Fromm (1900–1980) also described broadly similar authoritarian personalities whose basic needs attracted them to fascism. The most theoretically developed and empirically based of these explanations was proposed in 1950 by Theodor Adorno (1903–1969), Else Frenkel-Brunswik (1908–1958), Daniel Levinson (1920–1994), and R. Nevitt Sanford (1909–1995) in a monumental book, The Authoritarian Personality (1950). This book reported a program of research that began with the aim of explaining anti-Semitism, but culminated in a far more ambitious theory, which for a time dominated social scientific inquiry into the psychological bases of prejudice and ethnocentrism.

Their first major finding was that anti-Semitic attitudes were not held in isolation, but were part of a broader ethnocentric pattern involving a generalized dislike of out-groups and minorities, excessive and uncritical patriotism, and politically conservative attitudes. Their research suggested that this pattern of attitudes seemed to be an expression of a particular personality syndrome consisting of nine tightly covarying traits. These were:

1. Conventionalism (rigid adherence to conventional middle-class values).
2. Authoritarian submission (submissive, uncritical attitudes toward authorities).

3. Authoritarian aggression (the tendency to be on the lookout for, condemn, reject, and punish people who violate conventional values).

4. Anti-intraception (opposition to the subjective, imaginative, and tender-minded).

5. Superstition and stereotypy (belief in mystical determinants of the individual’s fate, and a disposition to think in rigid categories).

6. Power and toughness (preoccupation with the dominance-submission, strong-weak, leader-follower dimension; identification with power; exaggerated assertion of strength and toughness).

7. Destructiveness and cynicism (generalized hostility, vilification of the human).

8. Projectivity (a disposition to believe that wild and dangerous things go on in the world; the projection outward of unconscious emotional impulses).

9. Sex (exaggerated concern with sexual “goings-on”).

Psychometric questionnaire items were developed in order to assess each of these traits, and these culminated in the famous F (“fascist”) scale, which was used to measure this “authoritarian personality” dimension. Research did indeed show that the F scale was powerfully correlated with measures of prejudice, ethnocentrism, conservative attitudes, and extremist right-wing politics.

Adorno and his colleagues theorized that authoritarian personalities originated from childhood socialization characterized by strict, punitive parental discipline and conditional affection. This creates an inner conflict between resentment and hostility toward parental authority and a fearful need to submit to that authority, which culminates in identification with, and submissive idealization of, parental authority, and by extension all authority. This aggression is repressed and displaced onto targets sanctioned by authority. These psychodynamics are expressed in the nine surface traits of the authoritarian personality, the pattern of ethnocentric, conservative, chauvinistic social attitudes, deference to established authority, and pervasive hostility and prejudice against out-groups, minorities, and other socially deviant targets.

This theory attracted enormous attention initially, and the F scale became widely used. Critics, however, noted methodological flaws in the research, and pointed out that the theory ignored authoritarianism of the Left. The F scale was found to have serious psychometric flaws, most notably the all positive formulation of its items so that scores were heavily contaminated by the response style of acquiescence (the general tendency for people to agree rather than disagree). When this was corrected, the items of “balanced” versions of the F scale lacked internal consistency, and so could not be measuring a single unitary syndrome or dimension. As a result of this, and other nonsupportive findings, interest in the theory and the F scale largely collapsed during the 1960s.

Since the mid-1980s, however, interest in the issue has revived with the identification of two distinct “authoritarian” individual difference dimensions that seem to underlie prejudice, intolerance, and ethnocentrism. First, in the 1980s Bob Altemeyer showed that three of Adorno and colleagues’ original traits—conventionalism, authoritarian aggression, and authoritarian submission—did constitute a unitary individual difference dimension, which he named right-wing authoritarianism and characterized as “submissive” authoritarianism. Second, in the 1990s Jim Sidanius and Felicia Pratto identified a second, “dominant,” authoritarian dimension, seemingly relating to Adorno and colleagues’ original traits of power, toughness, destructiveness, and cynicism, which they called social dominance orientation. The idea that these might be personality dimensions, however, has been challenged, and it has been argued that they seem better viewed as ideological attitude or value dimensions that are influenced by personality, but are not in themselves personality dimensions.

**PERSONALITY, CULT OF**

*Cult of personality* is a pejorative term implying the concentration of all power in a single charismatic leader within a totalitarian state and the near deification of that leader in state propaganda. Totalitarian regimes use the state-con-
trolled mass media to cultivate a larger-than-life public image of the leader through unquestioning flattery and praise. Leaders are lauded for their extraordinary courage, knowledge, wisdom, or any other superhuman quality necessary for legitimating the totalitarian regime. The cult of personality serves to sustain such a regime in power, discourage open criticism, and justify whatever political twists and turns it may decide to take. Among the more infamous and pervasive cults of personality in the twentieth century were those surrounding Hitler, Mussolini, Stalin, Mao Zedong, Francisco Franco, Chiang Kai-shek, Ho Chi Minh, Kim Il Sung, Juan and Evita Peron, Pol Pot, Augusto Pinochet, Kim Jong Il, and Saddam Hussein. The term is occasionally—if idiosyncratically—applied to national leaders who did not seek similar godlike adulation during their lifetime or term in office but have been later glorified by the government or in the national mass media. Examples might include George Washington, Napoléon Bonaparte, Abraham Lincoln, Vladimir Lenin, Mustafa Kemal Atatürk, Charles de Gaulle, Ronald Reagan, Margaret Thatcher, and others.

A cult of personality differs from Thomas Carlyle’s “hero worship” in the sense that it is intentionally built around the national leader and is often used to justify authoritarian rule. In one of the more idiosyncratic usages, it is sometimes applied by analogy to refer to the public veneration of famous leaders of social movements such as Karl Marx, Mahatma Gandhi, Martin Luther King Jr., Che Guevara, Malcolm X, Nelson Mandela, and others. In fact, the term itself derives from Karl Marx’s critique of the “superstitious worship of authority” that had developed around his own personality, acclaimed merits, and contribution to the work of the First Socialist International in the latter half of the nineteenth century.

Historically, numerous rulers have promoted their own cults of personality. Absolute monarchies were the prevalent form of government for much of recorded history, and most traditional monarchs were held in public awe and adoration. For example, pharaonic Egypt, Imperial China, and the Roman Empire accorded their crowned sovereigns the status of revered god-kings. The doctrine of the divine right of kings claimed that absolutist monarchs such as Henry VIII, Louis XIV, or Catherine the Great sat on their thrones by the will of God. The democratic revolutions of the eighteenth and nineteenth centuries made it increasingly difficult for traditional autocrats to retain their divine aura. However, the development of the modern mass media, state-run public education, and government propaganda has enabled some more recent national leaders to manipulate popular opinion and project an almost equally extolled public image. Cults of personality developed around some of the most notorious totalitarian dictators of the twentieth century such as Hitler, Stalin, and Mao, who at the peak of their personalistic power were lionized as infallible, godlike creatures. Their portraits were hung in every private home or public building, while the country’s artists and poets were expected to produce works of art idolizing the hero-leader.

Many lesser known autocrats have engaged in similar self-glorification, subordinating nearly all aspects of national life to their fickle vanity, megalomania, and conceit. In post-Soviet Turkmenistan, for instance, the late president-for-life Saparmurat Niyazov encouraged his own cult of personality, dotting the local landscapes with public monuments to himself and even renaming the months of the year to pay homage to himself and his family. After declaring Turkmenistan’s independence in October 1991, the former chairman of the Soviet-era Council of Ministers and first secretary of the Turkmen Communist Party quickly established himself as the center and source of all political authority in the new country. Niyazov became the first president of independent Turkmenistan and won the uncontested 1992 election, which was the only presidential election held during his rule. He assumed the title of Türkmenbaşy (“head of all the Turkmen”), and the country’s obedient legislature proclaimed him president for life. He even authored a book—the Ruhnama, or “Book of the Spirit”—that became a compulsory part of the curricula at all levels of the national educational system.

The term cult of personality became a buzzword after Soviet leader Nikita Khrushchev bitterly denounced Stalin’s near deification before a closed session of the Twentieth Party Congress on February 25, 1956:

The cult of personality acquired such monstrous dimensions mainly because Stalin himself, using all conceivable methods, supported the glorification of his own person…. One of the most characteristic examples of Stalin’s self-glorification and of his lack of even elementary modesty is the edition of his Short Biography, which was published in 1948. This book is an expression of the most unrestrained flattery, an example of making a man into a god, of transforming him into an infallible sage, “the greatest leader,” “sublime strategist of all times and nations.” Ultimately, no more words could be found with which to praise Stalin up to the heavens. We need not give here examples of the loathsome adulation filling this book. All we need to add is that they all were approved and edited by Stalin personally and some of them were added in his own handwriting to the draft text of the book. (Khrushchev 1989)

In a country long known for its traditional worship of religious saints and czars, the public exaltation of Soviet leaders was deliberately pursued as necessary for building national unity and consensus. The result was Stalin’s cult
of personality—the total loyalty and dedication of all Soviet citizens to the all-powerful leader, whose demigod personality exemplified the heroism and glory of “building socialism in one country.” Khrushchev’s “Secret Speech” was a major break by the post-Stalin leadership with the oppressive dominance of Stalinism. “Big Brother,” a fictional character in George Orwell’s famous novel Nineteen Eighty-Four, is widely believed to be a satire of Stalin’s cult of personality (even though it is equally likely to have been based on Britain’s ubiquitous Lord Kitchener).

PERSONALITY, TYPE A/TYPE B

The roles that personality and behavior play in illness and disease can sometimes be difficult to determine. Because specific personality or lifestyle characteristics cannot be randomly assigned to people, researchers must rely on longitudinal and prospective studies. In these studies, factors that are suspected to be related to disease proneness must be shown to predict health outcomes, sometimes by following participants for a period of many years. In the late 1950s, two California cardiologists named Meyer Friedman (1910–2001) and Ray Rosenman proposed a specific personality type that, based on their clinical experiences, seemed to be associated with high frequencies of cardiovascular disease. In 1960, Friedman and Rosenman began the Western Collaborative Group Study. In this longitudinal study, the researchers followed over 3,000 healthy adult males aged 39 to 59 for more than eight years. Their goal was to determine the relationships among personality, behavior, and the development of heart disease.

At the start of their study, Friedman, Rosenman, and their colleagues conducted 15-minute structured interviews that focused on both verbal and nonverbal behaviors. Participants answered questions about everyday events, such as waiting in lines, driving in traffic, and dealing with problems at home. In addition, interviewers assessed how loud and fast participants spoke during the interview and how they reacted when they were deliberately interrupted during the interview. Based on these taped interviews, the researchers identified different patterns based on a combination of physical, emotional, psychological, and behavioral indicators. Among these patterns was what the researchers called the Type A pattern, the Type B pattern, and mixtures of the two types.

TYPE A AND TYPE B

Physical indicators of Type A Behavior Pattern (TABP) include excess perspiration; facial muscle tension and tics; high levels of alertness and hyperactivity; high levels of epinephrine and norepinephrine (hormones associated with stress); and increased heart rate and levels of diastolic and systolic blood pressure. Emotional indicators include high levels of stress, irritation, hostility, anger, and aggression (especially under provoking conditions). Psychological indicators include impatience; strictness, rigidity, and perfectionism; low tolerance for mistakes; low self-esteem; personal insecurity; compulsiveness; and a high need for control. Finally, examples of behavioral indicators include a general sense of time urgency; losing one’s temper while driving; speaking loudly and quickly; interrupting other people’s speech; teeth and tongue clicking; a chronic focus on success, ambition, competitiveness, and achievement; and workaholism.

Early proponents of TABP sometimes referred to it as the “hurry sickness,” in order to highlight those factors related to the perception of and use of time. Several TABP indicators are thought to be influenced by European and North American social, cultural, and economic values. For example, job promotions and social prestige may often be tied to how much Type A behavior a person shows. The work climate and demands of many kinds of jobs may also reinforce Type A behaviors.
In contrast to the Type A pattern, Type B behavior pattern is characterized by a more calm and even-tempered demeanor. With regard to physical indicators, Type B individuals show more muscle relaxation and lower levels of activity and alertness. Emotionally, such personality types show less frequent irritation, anger, hostility, and aggression than Type A individuals. Psychologically, Type B persons are methodical, tolerant of mistakes, and personally secure. Finally, Type B individuals are more cooperative and relaxed and less achievement-oriented than their Type A counterparts. In the Western Collaborative Group Study, the TABP proved to be a significant predictor of coronary heart disease (CHD), with Type A men showing almost twice the risk of developing CHD than Type B men. In that study, the TABP predicted increased incidence of CHD independent of other risk factors such as smoking, exercise frequency, and parental history of heart disease.

REFINEMENT OF THE TYPE A CONCEPT

As these findings were publicized and tested more fully, several concerns arose regarding the original conception of TABP. First, questions about the best way to assess the pattern emerged. In an effort to assess TABP more efficiently than through the time-consuming individual structured interviews, researchers developed several self-report measures. For example, the multiple-choice Jenkins Activity Survey (JAS), developed in 1979, assesses many of the attitudes and behaviors originally identified as comprising the TABP. However, concerns have arisen about how well the JAS and other measures capture the major dimensions of TABP. For instance, the JAS devotes less attention to the hostility component than seems to be warranted, and scores on the JAS are only weakly related to incidence of CHD. Nonetheless, this measure continues to be the most frequently used instrument in studies of the TABP. More recently, some researchers have utilized videotaped structured interview protocols.

Although the original formulation of TABP was intuitively appealing, one of the problems with such a broad and overly inclusive definition is that many (sometimes the majority) of participants in a study had been labeled as meeting the diagnostic criteria of TABP. As researchers continued to examine the links between personality and CHD, some studies were also unable to replicate the earlier findings of Friedman and Rosenman. In addition to facilitating the development of new and different measures, the concerns about diagnostic criteria led to a detailed examination of the major components of TABP. Given the large number of behaviors that can make up the Type A pattern, it is not surprising that some of these do not necessarily occur together with others. Researchers thus began to focus their attention on which components of the original multifaceted TABP were (and were not) associated with negative health outcomes.

With these more sophisticated studies, researchers discovered that hostility, especially antagonistic or angry hostility, appeared to be the TABP component that was most strongly related to CHD. In other words, people showing chronic levels of anger and hostility as well as negative affect (in particular depression and anxiety) are more likely to develop CHD. On the other hand, levels of achievement motivation, impatience, and workaholism failed to predict CHD. In addition, subsequent research showed that the perception and use of time turned out to be less predictive of negative health outcomes than other parts of TABP. A 2006 study showed that negative affectivity (i.e., the frequency of negative emotions) and a socially dominant interpersonal style can play a role in a variety of poor health outcomes.

Researchers have also attempted to determine how the psychological components of the TABP develop and how they contribute to the development of CHD. Along these lines, some research suggests that Type A children react more strongly to stress than do Type B children. Researchers have also demonstrated that hostility and aggression are related to cardiovascular response and future risk level in children. Other research suggests that Type A characteristics are likely to develop through a combination of children’s temperaments and parental behaviors. For example, children who show the competitiveness associated with the TABP may be encouraged by their parents to perform well in achievement settings, possibly making them more prone to anger and hostility.

In the last decade, researchers have examined how the TABP might be related to social behaviors that are not specifically related to illness or disease. Examples of these behaviors include marital dissatisfaction, driving behavior, group performance, and work-related stress. Some researchers have attempted to apply TABP to companies and organizations. In addition, research has examined how TABP might interact with situational factors, specific kinds of stressors, and various demographic variables (such as age and gender) in determining negative health outcomes. For example, Type A persons might be more likely than Type B persons to find themselves in situations or settings that create frustration, impatience, or irritation. Researchers have also begun to examine whether certain aspects of TABP might be caused by specific disease processes and to identify possible pathways through which personality might increase the likelihood of unhealthy behaviors that could contribute to disease frequency.

In other words, efforts to assess the relationships among personality, behavior, and disease have become more sophisticated and complex than the original TABP.
concept. As such, the interest, excitement, and promise relating to the original formulation TABP has waned considerably. This has led many modern day personality and health researchers and theorists to consider TABP concept to be no longer useful. Nonetheless, the initial study that identified Type A and Type B personalities, and the publicity it received, helped to energize the emerging fields of behavioral medicine and health psychology.

**PERSON-SITUATION DEBATE**

Many social scientists strive to understand why people do what they do. One traditional perspective in personality psychology suggests that people do what they do because of their personality traits. A trait psychologist might suggest, for example, that a person behaves talkatively because she has a high level of extraversion. Trait psychologists traditionally assume that traits are stable psychological characteristics, remaining quite consistent across situations and time. By implication, the trait approach assumes that an individual’s behavior should be fairly consistent across situations and time.

In 1968 Walter Mischel published a book challenging the foundations of the trait perspective. Mischel reviewed empirical examinations of behavioral consistency, and he claimed that results revealed surprisingly low levels of cross-situational consistency. He concluded that a theoretical perspective based on broad, context-free personality traits was too simplistic, and his conclusions became the basis of the “situationist” position that human behavior is strongly determined by situational forces.

The debate between those sympathetic to traditional personality psychology and those representing a situationist position became known as the person-situation debate. The nature of the debate ranged widely, with protagonists from both sides taking positions of varying extremity, accusing each other of undue extremity and of misinterpretation or misrepresentation of the opposing position. For example, proponents of the “situationist” side variously suggested, or at least were accused of variously suggesting, that the traditional trait approach was too simplistic, that traits do not exist, or even that personality itself does not exist. Despite such ambiguity on both sides, at its heart the debate concerned two important issues—the nature of the behavioral phenomena to be explained and nature of the theories offered as explanations of behavior.

One fundamental issue in the person-situation debate was the degree to which stable individual differences in behavior exist alongside cross-situational variability in behavior. At least two developments advanced the field’s understanding of the empirical realities of behavioral stability and variability. First, research demonstrated that individuals do manifest stable differences in their general behavioral trends, if behavioral observations are aggregated across situations (Epstein 1979). Second, research demonstrated that considerable levels of behavioral stability and variability coexist (Fleeson 2001; Funder and Colvin 1991). That is, an individual does behave differently across a variety of situations; however, individuals differ from each other in their average levels of behavior, and these individual differences are indeed stable. These findings are important because they empirically demonstrate, within a single set of behavioral data, the validity of the assumptions of both the trait position (that people manifest stable differences from each other in their behavior) and the situationist position (that people’s behavior varies across situations). The fact that both the trait side and the situationist side are empirically tenable legitimizes the theoretical basis of both.

A second important issue in the person-situation debate was the theoretical basis of personality psychology. Psychologists debated the appropriate ways to conceptualize personality and its ties to behavior. Emerging from two or three decades of debate, most theories are “interactionist” because they acknowledge the fact that behavior results from an interaction between personality and situational forces. Despite the general agreement that personality and situational forces affect behavior, such theories differ in terms of the nature and relative importance placed on such factors. Some theorists are sympathetic to an expanded trait perspective. Such theorists acknowledge...
the role of situational forces in shaping specific behaviors, but they emphasize the utility of traits as predictors of important behavioral trends and outcomes such as psychological well-being, physical health, social relationships, occupational performance, and political attitudes (e.g., Costa and McCrae 1998; Ozer and Benet-Martinez 2006). Other theorists reconceptualize personality in terms other than “traits.” For example, the social-cognitive approach emphasizes the importance of cognitive characteristics affecting the way people process information about social situations. From this perspective, cognitive personality characteristics such as one’s expectations, beliefs, or self-concept are indeed stable, but different situations trigger different aspects of the cognitive system, leading to variability in behavior (Mischel and Shoda 1995). Finally, some theorists recognize the need for greater attention to the psychological nature of social situations (Funder 2005).

The person-situation debate was a challenging yet ultimately constructive argument for personality psychology (Fleeson 2004). By forcing psychologists to think carefully about the links between behavior, personality, and situations, the person-situation debate was a catalyst for a deeper appreciation of the importance of personality and for a more sophisticated understanding of why people do what they do.

PERSPECTIVE-TAKING

Perspective-taking—viewing the world from something other than one’s habitual vantage point—covers a broad range from the literal to metaphorical. One can literally take a visual perspective by physically positioning oneself and gazing in a particular direction, often replicating another person’s physical position and directional gaze in an attempt to see what that person sees (e.g., “Stand here and you can see the tower between the hills”). Alternatively, one can imagine a particular visual perspective (e.g., “These steps must look very tall to someone as short as a toddler”) or mentally construct a visual perspective (e.g., “Let’s see … facing east, I can see the house, so if I were to face west, I would see the street”). However, perspective-taking often goes beyond the visual, referring to attempts to adopt an overall mindset that differs from one’s default mindset (“Imagine what the rabbi must have thought when the caterers brought out all those trays of ham!” or “I can see your point—you could have used more time to prepare”).

A cornerstone of Swiss developmental psychologist Jean Piaget’s (1896–1980) theory of cognitive development was that human infants have just one perspective—their own. They are profoundly egocentric: unable to even comprehend that someone else may have a different mental experience from their own and thus unable to take another person’s perspective. As young children develop, they not only learn that other perspectives exist, but also how to take those perspectives and use them. Children who can recognize that other people have their own minds and can thus have other perspectives are said to have developed a theory of mind. In a typically developing child, a coherent theory of mind emerges between ages three and five (although rudiments of this skill, such as following another person’s gaze to understand what he or she is looking at, appear earlier). Theory of mind and perspective-taking deficits are among the hallmark symptoms of autism, a psychological disorder that usually appears early in life (other psychological disorders or brain injuries can also produce perspective-taking deficits).

Some scholars have argued that a true understanding of theory of mind may be unique to the human species. However, even for adult humans, perspective-taking requires effort and presents a challenge. Easy or perfectly accurate perspective-taking is hindered by the “other
minds problem”—that is, we can never know from a first-person perspective exactly how things are perceived by another person with another mind.

Perspective-taking has a variety of social implications. In both children and adults, perspective-taking is associated with greater empathy, prosocial behavior, and more favorable treatment of the person (or group) whose perspective is taken. The exact mechanism by which perspective-taking produces these outcomes is debated, with a variety of options proposed, including suppression of the usual “self”-ish perspective, a heightened desire to help the other person, attempts to relieve negative feelings aroused by perceiving another person in distress, and the cognitive merging of one’s representation of the self with that of the person whose perspective is being taken. Research consistently demonstrates that instructing people to take the perspective of another person in need leads to increased feelings of compassion and empathy and often results in offers to help the person whose perspective was taken. However, perspective-taking can also be used for malevolent purposes (e.g., anticipating a rival’s next move and taking steps to thwart it).

Since Piaget’s day, developmental researchers (e.g., Janet Astington, Simon Baron-Cohen, John Flavell, Alison Gopnik, Andrew Meltzoff, Joseph Perner, and Henry Wellman) have continued to ask questions about perspective-taking and its relationship to other aspects of human development. Social psychologists have also pursued perspective-taking and its effects on social behavior (notably Daniel Batson’s work on links between perspective-taking and altruistic behavior, and William Ickes’s work on adults’ perspective-taking and its relationship to other aspects of human development. Social psychologists have also pursued perspective-taking and its effects on social behavior (notably Daniel Batson’s work on links between perspective-taking and altruistic behavior, and William Ickes’s work on adults’ perspective-taking and its effects on social behavior). Most recently, neuroscientists (e.g., Jean Decety) have used brain-imaging techniques to explore perspective-taking.

**PERSUASION**

Every day we are exposed to hundreds of attempts to change our opinions. Consider how often you come across an advertisement—in a magazine or newspaper, on television, the radio, or a Web site. But marketers are not the only ones trying to influence us. Family members, religious leaders, politicians, and friends all try to convince us to do things, agree with them, or support their cause. Although persuasive attempts are pervasive, they are not always successful.

Persuasion can be defined as an active attempt by a person, group, or entity (such as a corporation), usually through some form of communication, to change a person’s mind. Although we use the term *mind* here, often what we are referring to are attitudes or opinions. Persuasion has been a central focus of the social psychology literature at least since the mid-twentieth century—perhaps because persuasive attempts are so common. Furthermore, if attitudes can be changed, behavior can be changed as well.

**THE MESSAGE LEARNING APPROACH**

In the 1940s a group of researchers led by the psychologist Carl Hovland (1912–1961) at Yale University spearheaded a comprehensive program of research on persuasion. The catalogue of persuasive factors that they examined is now referred to as the *message learning approach*. The Yale group also proposed a sequence for the process of persuasion: in order for persuasion to occur, a person needs to be exposed to the persuasive message, as well as pay attention to, comprehend, accept or yield to, and remember the message. Although more recent researchers have argued that not all of these steps are absolutely necessary (particularly remembering the message), this basic process has been supported in numerous studies.

The Yale group also found that the source of the persuasive communication is an important determinant of success. The expertise and trustworthiness of the source are critical. For example, in an advertisement for basketball shoes, a professional athlete may be an expert but may not be trustworthy because he is being paid to sell the shoes. Thus the advertisement may not be effective. The attractiveness of the source is also important. This is why clothing advertisers use attractive models in their advertisements. The implicit message is: “If you buy these clothes, you will look good too.” Furthermore, the more you like someone and the more you are attracted to that person, the more likely you are to buy the product he or she is selling.

Characteristics of the persuasive message have also been explored. Factors that have been found to influence persuasion include: a one-sided versus a two-sided message (i.e., providing one or both sides of an argument); the order of messages; the comprehensibility of the message

**Sara D. Hodges**
content; and the number of arguments presented. In terms of the sidedness and order of messages, which is superior depends on the situation. Nonetheless, it is clear that if people do not understand the message they are exposed to, they will not be persuaded. For this reason, print advertisements for complex products (such as computers or stereos) are often more effective because people have the time to read and understand them. With regard to the number of arguments, more arguments usually result in more persuasion.

Characteristics such as the intelligence, self-esteem, and gender of the recipient have all been explored as factors affecting persuasion, but the results of these studies are mixed. In general, the more intelligent a person is, the more likely it is that he or she will comprehend a message, but the less likely it is that the person will accept the message. Early studies found that women tend to be more easily persuaded, but more recent research suggests that one's knowledge about a topic is more important than gender.

TWO ROUTES TO PERSUASION

Despite hundreds of studies exploring the variables discussed above, results have not always been consistent. Sometimes variables matter and sometimes they do not. Furthermore, the change in attitude achieved by persuasive communication is often transitory. To address these issues, Richard Petty and John Cacioppo developed the elaboration likelihood model, which proposes that persuasion typically happens by one of two routes. They argue that the extent to which message-relevant arguments are elaborated is a key determinant of the success of a persuasive appeal. Elaboration is not simply the learning of the arguments, but involves scrutinizing, making inferences about, and evaluating the quality of those arguments.

In a number of experiments, researchers have shown that when elaboration is low, persuasion tends to occur through peripheral route processes. That is, persuasion occurs through features or characteristics of the persuasion context (referred to as cues) that are not directly related to the central merits of the arguments. Such cues include the attractiveness or expertise of the message source, the mood of the participants, and the number of arguments presented.

When elaboration is high, however, people attend to the central merits of the arguments (central route processing). If the arguments are of high quality (i.e., strong), people's attitudes are likely to change. However, if the arguments are weak, people will be able to counter them, and the message will not be effective. In order for elaboration to occur, however, two conditions must be met: (1) people must be motivated to scrutinize the message (they need to be involved, feel a sense of personal responsibility, or enjoy engaging in cognitive tasks); and (2) people must be able to scrutinize the message (they must have the requisite knowledge to process the information, and must not be distracted). Perhaps this is why most advertisements on television, billboards, and Web sites are structured around peripheral cues (using expert, trustworthy, attractive sources, or humor); since people do not typically scrutinize these types of advertisements, peripheral approaches may be more successful.

Attitude-change research continues to enjoy a central role within the social psychological literature. Furthermore, it is clear from the numerous applications of the attitude-change literature to our daily lives (for advertisers, marketers, politicians, and many others) that persuasion research will continue to be at the forefront of the field.

PERSUASION, MESSAGE-BASED

Does advertising plant product images in people's minds? Do the media influence outcomes of elections? Why do so many attempts to scare teenagers into protecting their health fail abysmally? Is persuasion a social good or a malevolent agent used by cunning connivers?

These questions strike to the heart of persuasion theory and research, a time-honored academic field that dates back to fourth century BCE when the ancient Greek philosopher Aristotle (384–322 BCE) developed the first systematic approach to persuasion, or rhetoric as it was known then. From Aristotle's era to our own, persuasion endlessly fascinates people because of its uncanny ability to powerfully influence human attitudes and the elusive relationship with truth and morality.
Persuasion is defined as "a symbolic process in which communicators try to convince other people to change their attitudes or behavior regarding an issue through the transmission of a message, in an atmosphere of free choice" (Perloff 2003, p. 8). Persuasion is fundamentally self-persuasion. We persuade ourselves to go along with what communicators suggest; unfortunately, self-persuasion can be both benevolent and malevolent, with the determination of what is malevolent or benevolent a function of the consequences of the action, the persuader's intentions, and social context.

The basic component of persuasion is the attitude, which the entity persuaders hope to form, influence, and reinforce. We have attitudes toward all sorts of topics, from politics to religion. Attitudes have a cognitive structure and serve psychological functions for individuals. Attitudes can be weak (e.g., one's attitude toward the candidate running for state auditor) or strong (e.g., prejudice against African Americans). Attitudes predict behavior when the attitude is strongly held and is measured at the same level of specificity as the behavior.

Persuasive communications can change attitudes by employing appealing communicators, by developing a convincing message, or by containing features that attract attention but are peripheral to the message (e.g., music that accompanies an advertisement).

The key characteristic of effective communicators is credibility. Credible communicators are perceived to possess expertise, trustworthiness, and good will. Communicators also change attitudes because they are likable, physically attractive, or perceived as similar to the audience. Because charming, likable persuaders can take advantage of naive individuals, psychologist Robert Cialdini (2001) refers to these communicator traits collectively as "the friendly thief."

What you say and how you say it are aspects of the persuasive message. Evidence and statistics strengthen the persuasiveness of a message. Emotional factors, such as fear, also can sway audiences. A speech arousing fear (e.g., on cigarette smoking or drugs) can influence audience members if it scares them, points out negative consequences of performing a behavior, and identifies ways to avoid these consequences. Communications are also persuasive when they provoke inconsistencies—or arouse cognitive dissonance—between attitudes people harbor and their behavior.

Language is a key component of the persuasive message. The words you use, how fast you speak, and the metaphors you employ to frame your message can influence attitudes. Communicators who do not qualify or hedge their verbal statements are seen as more credible than unassertive speakers. Messages containing metaphors produce greater attitude change than those without metaphoric statements. We all can think of books, movies, and songs that changed the way we looked at the world, in large part due to the metaphors they employed and the stories they told (Green and Brock 2005).

Persuasion occurs in different contexts—one-on-one, as when a salesperson tries to sell you a car, and in groups, such as a business meeting or a jury. Interpersonal persuasion frequently occurs in stages, and persuasion professionals frequently resort to such techniques as foot-in-the-door, door-in-the-face, and lowballing. Today, much persuasion occurs through mass media, and a great deal of money is spent on research to understand consumers’ attitudes toward products and politics. Advertisements link products with fantasies in the hopes of convincing people that the product will bring them happiness or success. Politicians hire consultants who help them frame messages in politically palatable ways.

Scholars study persuasion by developing theories and testing hypotheses through empirical research. Contemporary theories, such as the elaboration likelihood model focus on process, emphasizing that persuaders cannot develop an effective message unless they appreciate how audiences think about the topic at hand. When individuals lack motivation to consider an issue, they process the message superficially, which suggests that simple messages with appealing images will carry the day. When people are more psychologically invested in a topic, they think more deeply about underlying issues. Under these circumstances, more complex or value-based messages influence attitudes (Petty and Cacioppo 1986).

Persuasion has great potential to help people change prejudiced attitudes and adopt healthier lifestyles. Unfortunately, human nature being what it is, unsavory communicators will continue to exploit persuasion to achieve their own ends. An educated citizenry should understand the processes by which persuasive communications induce individuals to alter their attitudes and behavior.

Petroleum Industry

The documentary evidence for the human use of petroleum begins with the Old Testament books of Genesis and Exodus and the works of the ancient Greek historian Herodotus (c. 484–430/420 BCE). In addition archaeologists found pitch in the tombs of the Egyptian kings Tutankhamen (c. 1370–1352 BCE) and Seti II (c. 1200 BCE). The Toltecs of Mexico used bitumen to set tiles as early as 1200 CE, and Native Americans dug oil wells in what are now Pennsylvania, Kentucky, and Ohio.

Still, until the 1850s there was no petroleum mining or production. In that decade oil wells were drilled specifically seeking petroleum in Poland, Canada, and the United States. By 1900 petroleum had been discovered in Baku (in present-day Azerbaijan), Poland, France, Scotland, Italy, Romania, Egypt, Canada, the United States, Mexico, Sumatra, Trinidad, and Peru. In the twentieth century discoveries were made on every continent and in most countries.

The Modern Petroleum Industry

The first modern use of petroleum was for kerosene, discovered in 1852. A kerosene lamp was invented in 1857, and the first kerosene factory was built near Baku in 1859. Gasoline was a by-product of kerosene production. After 1901 most petroleum was used for fuel oil to heat and light buildings and for gasoline to power automobiles with internal combustion engines.

From a macroeconomic perspective, petroleum is an intermediate good, consumed only to produce final consumption items. Despite the emphasis in the mass media on gasoline consumption and prices, the most extensive use of petroleum products since 1949 according to the U.S. Energy Information Administration has been for combined heat and power for homes and industry. Petroleum products thus enter the production functions of every home and industry in the economy. The amount value of petroleum products consumed in the United States in 2005 was 1,836,392 thousand barrels per day.

Industry Structure

The modern petroleum industry is structured into four types of organizations: (1) state enterprises, (2) multinational corporations, (3) the Organization of Petroleum Exporting Countries (OPEC), and (4) legally organized commodity exchanges. In most petroleum-producing countries in the early twenty-first century, the state owns a petroleum company with a legal monopoly on the production and distribution of crude petroleum. The largest of these after 1918 was the Soviet state petroleum enterprise.

Most crude petroleum is produced by Western companies. In 1870 the Standard Oil Company was created by the Rockefeller brothers and two other partners. In 1893 the Standard Oil Trust was formed in New Jersey to evade an antitrust suit brought by the state of Ohio. Gulf Oil Corporation was formed in 1901 by the Richard K. Mellon family. Texaco was founded as the Texas Company in 1901 by Joseph S. Cullinan, Walter B. Sharp, and Arnolds Shaect. The U.S. Supreme Court in 1911 ordered Standard Oil Trust dissolved. The component companies, still with the plurality of shares owned by the former Rockefeller shareholders, continued to operate as ostensibly separate companies. These companies were Standard Oil of Ohio, Standard Oil of Indiana, Standard Oil of New York, Standard Oil of New Jersey, Standard Oil of California, Standard Oil of Kentucky, Atlantic, and the Ohio Oil Company (later Marathon).
The Royal Dutch Company for the Exploration of Petroleum Sources in the Netherlands Indies was established in 1890. It merged in 1907 with Shell Transport and Trading Company, a British company, to form Royal Dutch Shell. The British government formed the Anglo-Iranian Oil Company in 1914. This company ultimately became British Petroleum. In 1924 the Compagnie Francaise des Pétoles was established by the French government. ELF began before World War II (1939–1945) with the establishment of three small companies to explore for gas near oil seepages in Aquitaine. Italy in 1926 formed Agencia Generale Italiani Petrol (AGIP). In 1953 ENI was founded as a conglomerate of thirty-six subsidiaries, including AGIP.

These companies all were multinational, multidivisional, and vertically and horizontally integrated firms. Within each company, five major functions were performed—exploration, drilling and production, transportation, refining, and distribution to final consumers. Subsidiaries were responsible for each function. Transfers of product among these subsidiaries and other divisions of the companies were accomplished using shadow pricing or some other form of transfer pricing. Actual payments were made only for transactions with outside firms.

OPEC was established in Baghdad in September 1960 as an intergovernmental organization of five original member states—Iraq, Iran, Kuwait, Saudi Arabia, and Venezuela. Its charter required that each member acquire an increasing level of control of production. By 1970 each member state was required to own a minimum of 55 percent of foreign petroleum companies operating within its jurisdiction. Iraqi production has not been part of OPEC quota agreements since March 1998 due to U.S. and United Nations controls. Other OPEC members have included Qatar (joined 1961), Indonesia and Libya (1962), Ecuador (1963–1993), Trucial States of Oman (now United Arab Emirates, 1967), Algeria (1969), Nigeria (1971), Gabon (1975–1995), and Angola (2007). The OPEC cartel was formed to control the world oil supply so as to increase revenue to member states. It operates by assigning members an annual supply quota for crude oil production and export. In 2005 it controlled about 41.7 percent of world production. OPEC also sets prices.

THE ERA OF THE SEVEN SISTER COMPANIES, 1911–1980

The name seven sisters was coined in a 1961 Time magazine article to refer to the dominant firms in the world oil industry: Royal Dutch Shell, Anglo Persian Oil (Anglo-Iranian Oil/British Petroleum/BP), Gulf Oil, Texaco, and three of the Standard Oil companies from the 1911 trust dissolution—Standard Oil of New Jersey (Humble Oil [Esso]/Exxon), Standard Oil of New York (Socony/Socony-Vacuum/Socony-Mobil/Mobil), and Standard Oil of California (Socal/Chevron). With the exception of Royal Dutch Shell, which is British and Dutch, these are all U.S. or British companies. Only the U.S. companies had their own significant domestic supply sources in the founding period of the industry from 1850 to 1950. The British and Dutch thus undertook a worldwide search for sources, beginning with their colonies and extending after World War I (1914–1918) to the League of Nations territories mandated to their administration. The seven sisters and Atlantic Richfield (ARCO), called majors, were vertically integrated, and all had similar structures. They had separate subsidiaries for exploration, production, refining, and distribution and geographic subsidiaries for operations in different areas.

The most important “independent” or nonintegrated companies, which did not operate in at least one of the areas defining the integrated companies, in this period included Getty, Phillips, Signal, Union, Continental, Sun, Amerada Hess, Cities Service, Marathon, Compagnie Francaise des Pétoles, Occidental, ENI, Tenneco, and Skelly Oil. In 1983 Occidental acquired Cities Service. Texaco acquired Getty in 1984.

Soviet Petroleum Industry

The petroleum industry in Russia prior to the Bolshevik Revolution of 1917 was operated largely by U.S., British, and Swedish companies. During the seven sisters period, the Soviet state owned and operated the industry. The industry returned to private hands after 1991. ConocoPhillips acquired 16.8 percent of Lukoil, the largest Russian oil company. BP-Amoco invested in both Lukoil and Sidanko.

NATIONALIZATION, 1970–2000

Around 1912 producing countries began nationalizing or expropriating the ownership of foreign companies. The theoretical basis for expropriation was provided by Marxism-Leninism. The acceleration of this policy after 1970 was due more to nationalism, although the regimes that instituted it were almost always leftist. Majority or full expropriation took place in Argentina (1912), the Soviet Union (Baku, 1918), Mexico (1938), Iran (1951), Indonesia (1950s–1960s), Egypt (1961–1964), Peru (1968), Libya (1971), Nigeria (1971), Iraq (1972), Algeria (1972), and Saudi Arabia (1973).

CONCENTRATION AND CENTRALIZATION

Since the 1980s there has been an acceleration in the rate of concentration and centralization in the world oil industry with the development of what are referred to as supermajors, majors, and independents or jobbers. Supermajors
consist of BP-Amoco, Chevron-Texaco, Exxon-Mobil, ConocoPhillips, and Shell. This category of companies is defined as having a capitalization of $100 billion or more. Majors are defined as companies having a capitalization of $30 to $100 billion. Independents and jobbers include those with a capitalization of less than $30 billion. Supermajors have largely abandoned their traditional function of exploration, 80 percent of which now is conducted by independents. They receive most of their profits from the refining and petrochemical industries and also have diversified into alternative sources of energy, including atomic energy.

Simultaneously with this centralization and consolidation, many countries opened up their petroleum industries again to private international companies. Conflicts between source countries and companies extracting crude petroleum have been endemic from the beginning of the modern era, and examples such as the conflict in southeastern Nigeria and the war in Iraq are manifestations of this phenomenon.

Environmental issues in the extraction and transportation phases of the industry’s operation are less visible and perhaps less important than in the consumption phase. For this reason this issue has been the most recent to emerge. However, the environmental impact of the international industry is difficult to measure systematically, for no international statistics on this issue are collected. The number and volume of oil spills are available, but these represent only extraordinary occurrences, not the everyday degradation of the environment due to operations.

THE POLITICAL ECONOMY OF THE PETROLEUM INDUSTRY

During World War I and continuing into the early twenty-first century, Western countries transformed their economies and their military forces to use petroleum as the primary fuel source. As they did so diplomatic and military conflicts arose over control of the known sources of petroleum. Because this transformation was not far advanced until after World War I, that war cannot be characterized as a war over oil.

Most of the known sources at the beginning of this period were in the United States. Elsewhere oil production began in Baku in the 1870s, in the Dutch East Indies in 1883, in Iran in 1908, in Egypt in 1910, in Venezuela in 1914, in Kurdistan (now part of Iraq) around 1915, in Iraq in 1927, in Saudi Arabia in 1935, in Libya in 1959, in Egypt in 1966, in Sudan in 1974, and in Kazakhstan in 2000. These sources were discovered by Western oil companies, which have involved their governments in protecting their exploitation of these resources.

Local and Regional Conflicts Many of the conflicts that arose were local or regional, involving antagonistic political and military forces internal to countries with petroleum reserves, or between neighboring countries with at least one having reserves. These conflicts took the form of rebellions, revolutions, coups d’état, civil wars, and border wars. For example, in the failed 1905 revolution in Russia, the Baku fields were set afire. The Kurds, representing Turkey, massacred millions of Armenians during World War I. In 1929 and 1989 civil wars occurred in Afghanistan. In 1945 a coup in Venezuela gave control of the oil fields to a different power group in the country. Petroleum has been associated with two civil wars (1955–1972 and 1983–2005) and an armed rebellion in Sudan. The Nigeria-Biafra civil war (1967–1970) involved petroleum fields in the Niger Delta. The Angolan civil war (1976–2002) involved petroleum reserves in the Cabinda enclave. And a rebellion that began in Darfur in 2003 involved the South Darfur fields.

Local and regional conflicts increased significantly after Britain withdrew its naval forces from the Indian Ocean and the Persian Gulf in 1971.

Multinational and Global Conflicts Other conflicts involved the major European political powers of the day—the large petroleum-consuming countries—in conflicts that were considered to be major set-piece “wars.” Britain and Afghanistan fought three wars (1838–1842, 1878–1881, and 1919), the British attempting to thwart perceived Russian designs on British India, then including Pakistan. At that time petroleum had not been discovered in or near Afghanistan and so played little role in these wars.

After World War I, Turkey captured a part of the territory of the ethnic Kurds. Another part was given to Britain by the League of Nations as part of the Iraq mandate. A section of this territory was given to the French in the Syrian mandate. The Soviet Union captured the Azerbaijan part in 1920. Kurdistan was made a semiautonomous region of Iraq, the only Kurdish political entity internationally recognized. Turkey and the Soviet Union captured parts of the territory of the ethnic Armenians, other parts of which lie in northern Syria, Iraq, and Iran.

During the 1890s the British attempted to expand the border of their colony British Guiana (now Guyana) westward to include parts of Venezuela, where indications of oil had been discovered. This was probably unnecessary, because Guyana is a geologic sink, a lower-than-sea-level basin into which petroleum flows by gravity from Venezuela on the west and Dutch Guiana (now Surinam) on the east, so wells drilled in Guyana would draw from pools shared with Venezuela and Surinam. Nevertheless, British and German warships blockaded the ports of Venezuela until the United States, citing the Monroe
Doctrine, forced them to cease. Oil was discovered in 1914, and by 1928 Venezuela was the world's largest exporter of oil. Thus one sees the hand of Britain in the Afghanistan, Kurdistan, and Venezuela conflicts between the two world wars.

The most important of these major conflicts was World War II, the first war that might be characterized as an "oil war," with the petroleum resources of the Caspian Sea, the Persian Gulf, the Gulf of Mexico, the Caribbean Sea, Lake Maracaibo, and the Dutch East Indies being strategic targets of all combatants. As part of its strategy to defend the Caribbean Sea and the Gulf of Mexico from German attack, the United States concluded a deal with Britain in 1940 by which the United States gave Britain used destroyers in exchange for the right to use or build bases in the British Caribbean colonies.

North Africa was the location of battles between Italy and Germany on one side and Britain and the United States on the other to secure Persian Gulf oil, even though no oil had yet been discovered in Libya or the Western Desert of Egypt, where most of the battles were fought. On August 1, 1941, before its entrance into the war, the United States imposed an oil embargo on the Axis powers—Germany, Italy, and Japan. The Netherlands and Britain followed suit. The 1941 embargo reduced Germany's supply from Mexico and Venezuela and reduced Japan's supply from the Caspian Sea, the Persian Gulf fields, and the Dutch East Indies. The U.S. entrance into the war was largely due to its embargo of petroleum supplies to Japan. After negotiations with the United States, Britain and Holland failed to reverse this decision, and Pearl Harbor was attacked in December 1941 to reduce the U.S. capacity to enforce the embargo. Japan then invaded and occupied the Dutch East Indies (Sumatra, Java, and Borneo) from 1942 to 1946 to secure petroleum to fuel its war effort.

A few months after the war ended in 1945, a military coup took place in Venezuela, with control of revenues from oil production a major motivation for the conflict. The Dutch also fought wars in Indonesia to regain control of its colony but was forced to grant it independence in 1948. The cold war between the United States and the Soviet bloc from 1945 to 1991 involved the same strategic oil issues as World War II but did not rise to the level of open warfare. The Korean War (1950–1953) and the Vietnam War (1954–1975) were proxy wars for the United States and the Soviet Union but were less conspicuously concerned with control of petroleum reserves and their transportation to world markets. Importantly, however, with the exception of World War II, all conflicts over oil, both regional and global, took place in the countries in which the reserves lay, and not in the consuming countries. This changed dramatically with the onset of "terrorism."

**Terrorism** The rise of terrorism since the airplane hijackings in 1968—including especially the attacks on New York City in 1993 and 2001 and on the Pentagon in 2001, the bombings of U.S. embassies and ships in 1998 and 2001, and the bombings on Spanish and British trains and buses and other facilities in 2004 and 2005—changed the location of conflicts. Terrorism may be considered a form of guerrilla warfare, in contrast to a set-piece war. In response to this shift in theaters and tactics, Western governments alleged that certain Arab Muslim states were "sponsors" of these acts of terror or gave safe haven to terrorists. Western states directed military and economic sanctions against these states, which included Iran, Libya, Sudan, Somalia, Afghanistan, and Iraq. It is not without significance that all these states either have petroleum reserves or stand athwart transportation routes to world petroleum markets. Somalia, for example, controls the approach to the Red Sea and the Suez Canal.

In 1991 the former republics of the Soviet Union became independent. Several of them gave concessions to Western companies to explore for petroleum. With these discoveries, proposals were made for pipelines to carry the petroleum to shipping points for export to world markets. Three feasible routes exist for exporting Caspian Sea petroleum to world markets: west through Azerbaijan, Armenia, and Georgia to the Black Sea; south through Iran and Iraq to the Persian Gulf; or southeast through Afghanistan and Pakistan to the Arabian Sea. Overland markets are north into Russia and east into China.

All wars have as an objective the conquest of territory and its resources and assets, a major part since 1900 being petroleum reserves. Thus all wars since 1900 may be considered, to some extent, wars to control oil. This objective has attained the highest priority since World War II, leading to increased military and diplomatic conflict. Petroleum wars may be expected to continue to arise until a different energy source is discovered and widely employed or until an effective international nonviolent conflict resolution method is found and employed.

PETTIGREW, THOMAS F.

1931–

The American civil rights researcher and activist Thomas Fraser Pettigrew is one of the leading experts in the social science of race and ethnic relations to emerge in the post–World War II (1939–1945) period. Pettigrew received his B.A. in psychology from the University of Virginia in 1952 and both his M.A. (1955) and PhD (1956) in social psychology from Harvard University in the Department of Social Relations. His graduate training, requiring courses in sociology, social psychology, and anthropology, is reflected in the interdisciplinary perspective he has brought to over five decades of research on intergroup conflict. Pettigrew’s approach to social psychology was shaped by his mentor, psychologist Gordon Allport (1897–1967), and his classic 1954 text, The Nature of Prejudice. Other intellectual influences included sociologist and survey researcher Samuel Stouffer (1900–1960) and sociologist Talcott Parsons (1902–1979). Pettigrew’s experience of growing up white in the segregated South in the 1930s and 1940s further influenced his approach to prejudice and intergroup conflict by bringing him into close contact with the plight of African Americans.

Initially, Pettigrew studied the differences among white Americans in different regions of the United States. His research showed that psychological factors alone, in this case authoritarianism, could not account for the greater hostility toward blacks found among southerners. For a more complete picture, he argued for the importance of examining the structural components and the way in which societal norms hold bigotry in place. Pettigrew’s work continued to build on this insight, and he has argued throughout his career for the importance of studying social issues at several levels of analysis.

Pettigrew consolidated his theoretical position by developing a multilevel approach to social issues that combined the individual, the situational, and the societal levels, and the links among them. In the case of prejudice, there is the micro level of analysis, which includes individual attitudes, cognitions, and personality dynamics. There is also the macro level of analysis, including structural aspects of one’s society, its norms, and its mores. And finally, there is the meso level of analysis, in which the immediate situation of social interaction plays a key role. Throughout his career, Pettigrew has studied each level of analysis and its interaction with other levels, arguing that none is sufficient alone. Consequently, he has pursued research on authoritarianism and its relationship to prejudice, subtle prejudicial attitudes and their involvement in undermining societal desegregation, and the importance of friendship in his reformulation of contact theory and intergroup conflict. Pettigrew’s research is international in scope, with attention always paid to racial norms guiding the societies and their institutions (e.g., South Africa, the Netherlands, Germany) in which micro and meso factors are played out.

Pettigrew came into the study of social psychology with the intention of combining both scientific work and social activism. Throughout the 1960s and 1970s, he argued for an “honest broker” approach to the study of social issues, whereby social scientists, in a two-way dialogue with policymakers, would bring research to bear on social issues through, for example, pro bono expert testimony to courts and Congress, as well as policy-relevant research. Pettigrew has provided expert testimony on the positive effects of school desegregation to municipal, state, and federal levels of government. He has conducted research and consulted directly on implementation of policies and plans for desegregated schooling. Pettigrew’s work has always reflected the pulse of change in the United States for African Americans, as well as the resistance to change. He has researched, for example, white
attitudes to African American breakthroughs in public life at the grassroots level (e.g., the 1960s sit-in movement) and their candidacies as mayoral “firsts” in Gary, Indiana; Newark, New Jersey; Cleveland, Ohio; and Los Angeles. In his earliest books, A Profile of the Negro American (1964) and Racially Separate or Together? (1971), as well as more recent writings, Pettigrew has argued for an integrated society with data supporting its benefits in information and access for minorities.

As incoming president of the Society for the Psychological Study of Social Issues in 1967, Pettigrew pressured a reluctant American Psychological Association to provide a suitable forum for Martin Luther King Jr. (1929–1968) to address its annual convention, which King did to an overflow crowd of five thousand psychologists. Working with noted civil rights activist and scholar Kenneth B. Clark (1914–2005) on this and other civil rights projects through the latter’s Metropolitan Applied Research Center (MARC), Pettigrew continued research in the public domain at a time when the majority of social psychologists were focused on micro-level analyses of individual social behavior.

Pettigrew has never retreated from debate in both the academic and the public arena, and he is one of the most articulate defenders of the need for social scientists to engage with and make explicit their values. In 1975, at the beginning of the resegregation era, James Coleman (1926–1995) published a widely publicized study showing that school desegregation resulted in “white flight” to the suburbs. Pettigrew is well known for his critique of the Coleman Report, both its flawed science and the recommendations that ensued. While “white flight” was neither universal nor as damaging as thought, it provided judges with an acceptable reason for opposing urban school desegregation, turning back the gains of the desegregation era (1930–1973) and dismissing effective metropolitan solutions.

In the late 1970s, Pettigrew challenged the claim that race was declining in its significance relative to the rising role of social class, a claim put forward by sociologist William Julius Wilson. Pettigrew drew attention to the importance of the interaction of race and class, making racial discrimination only more subtle for upper-class African Americans. Reflecting back on the fiftieth anniversary of the U.S. Supreme Court’s landmark 1954 ruling in Brown v. Board of Education, Pettigrew argued for a rededication to efforts for preventing further resegregation in American society. By combining the best research with political and historical analyses, Pettigrew has demystified legal arguments for segregation, showing instead that separate educational facilities are inherently unequal and that intense residential segregation is a key element in the continued resistance to integrated schooling.

Pettigrew has maintained a prominent place as a scientist, teacher, public intellectual, and activist for over five decades. He has mentored numerous doctoral students, many of whom are renowned in their fields, including John Jemmott III, Howard Schuman, and Eliot Smith. He has collaborated with numerous colleagues internationally on issues of prejudice and discrimination toward immigrants in western Europe, most notably with Roel W. Meertens in the Netherlands and Ulrich Wagner in Germany. In addition, Pettigrew has held several appointments in sociology and social psychology, including appointments at Harvard University (1957–1980), the University of California, Santa Cruz (1980–1994), and the University of Amsterdam (1986–1991). He has been honored at many points in his career: as a fellow of the Center for Advanced Study in the Behavioral Sciences, Stanford University (1975–1976); with the Kurt Lewin Award of the Society for the Psychological Study of Social Issues (1987); with the Distinguished Scientist Award from the Society for Experimental Social Psychology (2002); and as a New Century Scholar, Fulbright Foreign Scholarship Board (2003). He served as president of the Society for the Psychological Study of Social Issues (1967–1968) and has been a longtime member of that organization, as well as of the American Sociological Association and the American Psychological Association.

PHALANGISTS

Phalangists are members of the Lebanese Phalanges Party (Hizb Al-Kata’ib Al-Lubnaniyyah). The Phalanges Party was founded in November 1936 by pharmacist Pierre Gemayel (1905–1984) and four other Christians in the wake of a visit to Germany, where Gemayel was a member of the Lebanese delegation to the infamous 1936 Olympic Games in Berlin. Gemayel never denied his desire to replicate the youth organizations of Nazi Germany, and the name was taken from Francisco Franco’s (1892–1975) Falange Española, a fascist political party. The Phalanges Party was founded as a response to the rise of “unionist” calls among Muslims and some Christian groups in Lebanon who sought the unity of Lebanon with either Syria or another Arab country as part of a larger Arab nation. Al-Kata’ib means “battalions,” a term that underlined the military purpose of the organization. In 1943 Phalanges leaders broke with Émile Edde (1886–1949), who wanted to preserve French rule in Lebanon, supporting instead the rising tide of popular sentiment that called for immediate independence. This position gave the party national legitimacy.

The party first fielded candidates in the by-election of 1945, but failed to win parliamentary seats until 1958, when the civil war boosted the popularity of the party among Lebanese Christians. As sectarian polarization tore the country apart, the Phalanges emerged as a well-organized party with a militia. Its recruitment and propaganda techniques became more sophisticated, and the party won six parliamentary seats in the 1960 election. It emphasized the ostensible uniqueness of Lebanon and resisted the Arabization of Lebanese culture and foreign policy. A Phalanges ideologue published a manual in 1966 pledging strict dedication to traditional values: God, homeland, and family. According to the manual, the party is also dedicated to democracy, private property, and the free enterprise system, and is opposed to individualism, leftist, and communism. Membership in the party was predominantly Christian, specifically Maronite, and the leadership was tightly in the hands of its founder, Pierre Gemayel.

The Phalanges Party established the most powerful militia in Lebanon as early as the 1950s, and the party attracted followers in the 1960s and 1970s by provoking clashes with Palestine Liberation Organization (PLO) forces. The clashes increased in the late 1960s when Phalanges armed men would ambush PLO trucks and cars in Kahhalah, a strategic Phalanges city on the Damascus-Beirut highway. The party was the major fighting force of the right-wing coalition during the 1975 civil war and received aid and weapons from Israel while its enemies were receiving aid from the PLO and other Arab countries. The rise of Bashir Gemayel (1947–1982, the son of Pierre) marginalized the party, although Bashir was also a leading member of the party. The civil war had many dimensions, but one of them entailed a PLO-Phalangist conflict. Many of the episodes of the conflict, including the siege of the Tal Az-Za’tar camp (and its destruction) and the Dbayy refugee camp in 1976, were Phalangist campaigns to root out the Palestinian presence in East Beirut.

The year 1982 was a watershed in the history of the party. First, Bashir Gemayel was elected president of Lebanon, but he was assassinated before he took office. After his assassination, militias loyal to the Lebanese Forces (a collation of right-wing militias under the control of the Phalanges) entered the Sabra and Shatila refugee camps and massacred hundreds of Palestinian (and some Lebanese) civilians. Bashir’s brother, Amin, became the first Phalangist to assume the presidency of the republic. In 1984 Pierre Gemayel died, and Amin insisted that Pierre’s deputy, Elie Karamah, a Greek Catholic, become the permanent leader of the party. Karamah’s tenure marked the ultimate marginalization of the party in Lebanese politics. In 1986 Georges Sa’dah, a Maronite, was elected to the presidency of the party, and he remained president into the 1990s, despite efforts to unseat him by his opponents and by a splinter faction headed by Karamah and supported by Amin Gemayel. The party boycotted the 1992 parliamentary election and did not win seats in the 1996 election. The Syrian government helped engineer a takeover of the party by a pro-Syrian faction headed by Karim Pakradoni, who served as a minister during the administration of Émile Lahhud. In 2005 Pakradoni all but surrendered the party to Amin Gemayel in recognition of his loss of popular support among Christian voters.

PHARMACEUTICAL INDUSTRY

The modern pharmaceutical industry in the United States originated during the 1818 to 1822 period when less than...
a dozen fine chemical manufacturers constructed factories in Philadelphia. History records Robert Shoemaker, producer of glycerin, as the first large-scale manufacturer in the period from 1818 to 1840. Medicines were previously manufactured in the laboratories of pharmacies where doctors and pharmacists compounded and administered drugs to patients and observed drug reactions. The Food and Drug Administration (FDA), which originated in 1902 by an act of U.S. Congress, regulates the modern pharmaceutical industry. (The agency is also a scientific and public health agency with oversight for the safety of most food products, radiation-emitting consumer products, cosmetics, and animal feed.)

Pharmaceutical firms are engaged in the discovery, manufacturing, and marketing of legal drugs, biologics (viruses, toxins, serums, and analogous products), vaccines, and medical devices such as pacemakers and prosthetics. Products are made for both humans and animals. Pharmaceutical products, both prescription and over the counter (OTC), account for a large share of the aggregate health care spending and represent major account items in international trade transactions of developed countries.

Pharmaceuticals as a percentage of total health care spending during 2002 comprised 12.8 percent in the United States, 14.5 percent in Germany, 15.8 percent in the United Kingdom, and 22.4 percent in Italy. Pharmaceutical spending in the United States grew at an average annual rate of 11 percent between 1970 and 2005. The industry is global and led all other industries in rent-seeking activities by spending nearly $1 billion from 1998 to 2004 on lobbying. Profit-seeking firms engage in strategic lobbying, a special case of rent seeking. Rent seeking is a selfishly motivated effort of one party (pharmaceutical firms) targeted at influencing another party’s (government regulators) decision. Economic agents will decide to invest in rent-seeking activities, such as lobbying, if the expected net present value of the effort is profitable at the margin. Global pharmaceutical trade grew at an average annual rate of 23 percent from 2000 to 2003 and was valued at $200 billion in 2002. More than 80 percent of pharmaceutical production and consumption occurs in North America, Western Europe, and Japan.

GENERAL CHARACTERISTICS
Several characteristics distinguish the pharmaceutical industry from other industries. A newly released pharmaceutical agent is usually available only by physician prescription. Patients in effect transfer decision-making authority on the appropriateness of medications for their ailments to the gate-keeping physicians (or pharmacists and nurses in some countries). Generally, a prescription may become available OTC (i.e., without physician prescription) for a non-chronic condition that is relatively easy to self-diagnose and has low potential for harm from self-medication under conditions of widespread availability.

Another important industry characteristic is the availability of health insurance coverage for prescribed medications. Most often, private insurers or government entities subsidize retail drug purchases. Consumers make a co-payment (a fixed sum for each prescription regardless of the full price) or pay a coinsurance (a fixed percentage of the full price) that is less than the full market price. Co-payments tend to vary depending on the drug classification. Consumer payment of far less than full cost of prescriptions creates the familiar “moral hazard” (excessive use) problem.

INDUSTRY GROWTH
The Centers for Disease Control (CDC) estimated that in 2005 more than 130 million Americans got prescriptions monthly. Physicians acting as the decision maker for patients and health insurance coverage of prescriptions create a market with fairly “inelastic product demand.” An inelastic product demand means that buyers’ percentage change in quantity purchase decisions are relatively insensitive to a given percentage price change that brought it about. Pharmaceutical product demand elasticity estimates vary depending on many factors, including the setting (e.g., inpatient versus outpatient or military versus noninstitutional population), brands versus generics, stringency of regulatory and provider reimbursements, and the strength of the consumption habits of consumers.

Some experts predict that the rise in insurance coverage is a major culprit in the undisciplined rising consumption of prescribed drugs. Other experts contend that the growth in prescription drug use is partly a function of greater marketing efforts of the drug firms. The pharmaceutical industry in 2003 spent $3.3 billion on direct-to-consumer advertising and marketing expenditures totaled $25.3 billion. Doctors’ prescribing habits are directly influenced by the probability of patient noncompliance, and advertising targeted at doctors and patients. Direct-to-consumer advertising reportedly slowed noncompliance rates. The U.S. drug firms spend a similar percentage of their sales revenue on advertising as on research and development.

The pharmaceutical industry manufactures innovative products with government-granted patent rights that may be extended after application approval from the FDA. Patents give researchers and inventors exclusive rights to market an invention for twenty years before others may duplicate and sell it. Therefore, producers of new drugs are free to limit the supply and set prices that reflect profit-maximizing mark-ups with exclusive marketing rights. Most pharmaceutical manufacturers in the United
States are multinational enterprises operating globally across countries. In 2004 the Pharmaceutical Research and Manufacturers of America (PhRMA) recorded drug sales of $159 billion within the United States and $79 billion abroad. The industry boasts investment rate of return that is four times the magnitude of the typical Fortune 500 firm. Technological progress in this industry and in the broader health care sector has led experts to project the global pharmaceutical market sales to be $842 billion in 2010.

There were more than 700 companies operating in the “pharmaceutical preparations” industry in 2006. The leading ten firms accounted for more than 40 percent of total industry sales. Other factors in this industry include retail pharmacies, health care provider institutions, and wholesalers. According to a 2000 report, the pharmaceutical industry earned 80 percent of the drug sales directly from wholesalers, 12 percent from retailers, and 4 percent from hospitals. Consumers typically buy drugs from retail pharmacies but there has recently been a rising trend in purchased drug activities via the Internet and from mail-order services within and outside the United States. Prescription drug buyers consider nontraditional purchasing outlets more convenient and private relative to traveling to a retail drugstore. Physicians may suggest Internet pharmacies to some homebound patients in order to improve compliance.

**RESEARCH AND DEVELOPMENT (R&D)**

In the United States new drugs must be approved by the FDA. In order to satisfy safety and benefit considerations of the FDA, pharmaceutical companies conduct on average ten to fifteen years of research on a new medication. Approval of a new drug is a rigorous process and for every 5,000 to 10,000 compounds tested, only one receives FDA approval and becomes a new or improved treatment. The entire U.S. pharmaceutical industry spent an estimated $51.3 billion on research and development in 2005. Nearly 80 percent of global R&D spending takes place in the United States and the major portion of the remaining 20 percent occurs in Europe.

The drug discovery process begins with the screening of thousands of compounds and modifying them to raise disease-fighting activity and/or minimize undesirable side effects for patients. Both laboratory and animal studies may be used to evaluate a drug's safety and efficacy during pre-clinical testing. Investigational new drugs go through a rigorous review by the FDA before moving to the clinical trials stage. Clinical trials of new medicines occur in three testing phases. Phase I includes drug tests in a small group of about 20 to 100 healthy volunteers to determine safety. During Phase II, 100 to 500 volunteer patients participate in controlled trials to determine whether the medicine effectively treats the disease. Phase III includes 1,000 to 5,000 patients taking the new drug and being monitored to confirm effectiveness and identify any side effects with comparison to patients in the placebo (inactive substance) group.

Drug development responds to the urgency and intensity of consumer demand, and economic harm, measured by disease-specific mortality, in the United States largely motivates the global distribution of drug development. The FDA approved 28 new drugs in 2005 and more than 350 medications became available for treating patients in the last decade. New medicines in development in 2006 included 682 to treat cancer, 531 to treat neurological disorders, 341 to treat infections, and 303 to treat cardiovascular disorders. One study in 2005 reported that new drugs generated 40 percent of the two-year gain in life expectancy achieved in 52 countries from 1986 to 2000.

When a company's patent rights expire, other companies can imitate the drug and produce generic brands of the medication. According to PhRMA, the generics' share of the U.S. prescription drug market was 57 percent in 2005. This share is expected to rise within the next decade as the rate of brand patent expirations increases.

**ECONOMIC FEATURES**

The discovery and manufacture of new drugs is a risky business without guaranteed profitability. The cost of developing one new medicine is estimated to be about $800 million (higher if genetically engineered) and on average, only three of every ten prescription medications available to treat Americans generate revenues that meet or exceed average R&D costs.

In the absence of patent protection, imitators could copy the new medication and manufacturers would lack practical incentives to invest millions of dollars on R&D of new drugs. Although patents nominally last for 20 years, the average effective patent life of prescribed medicines is only about 11.5 years due to time lost during the development and distribution of the new medicine to the market. Patent protection gives pharmaceutical manufacturers a monopoly status although generic drug makers can start preparing copies of drugs for FDA approval before patent expiration. A monopoly provides the patent owner with the sole right to manufacture the drug and determine the quantity to supply (hence the market price) according to its projected profit margin. The Treaty of Marrakech, signed in 2004 during the international trade negotiations, provided full patent protection for pharmaceutical products across industrialized nations as well as in the less-developed nations.

The pharmaceutical sector is controlled or strictly regulated by the government acting as a single buyer (payer) or a monopsony in countries with nationalized...
health systems (e.g., Canada, the United Kingdom). There are many end-users but they buy at government-regulated prices. Governments can regulate drug prices in a variety of ways. The most common methods of price regulation are reference pricing, formula pricing, capping or budgetary control, profit regulations and item-by-item negotiation. Reference pricing is a reimbursement rule where the government sets the maximum reimbursement for one drug by reference to the price of a comparable drug in the same market. Under formula pricing, governments use a wide criteria set, such as therapeutic novelty, to set drug prices. Capping or budgetary control would involve limiting reimbursement to the providers at a certain capitated level.

Other regulatory instruments generally target the profit margins of pharmaceutical companies and quality of manufacturing practices. For example, a 1990 law in the United States required drug manufacturers to apply on retail Medicaid prescriptions the largest discount they give any purchaser (the Medicaid drug rebate program). The U.K. government has used a rate of return regulation in which each firm negotiates with the government an allowed before-tax rate of return on its assets. Germany has used aggregate budget constraints and rollbacks. In this application, the government sets a tight overall budget and any amount above this budget would be deducted from payments to a third party (e.g., from the incomes of physicians, from the reimbursements to the drug manufacturers). These are all examples of government regulations to control drug prices and regulate excess profitability in the pharmaceutical industry.

The future pharmaceutical industry faces multifaceted challenges that include setting and enforcing manufacturing standards; rapid patent expiration of widely used brand drugs; unregulated parallel trades (re-importation in the European context) that ignores intellectual property rights; highly fluid and unregulated Internet sales; shortage of pharmaceutical scientists; biotechnology drugs and genetically engineered products (As of 2006 the FDA had no generics approval process in place for patented biotechnology drugs whose patents are about to expire); ineffective post-marketing surveillance; foreign manufacturing, regulatory, and pricing challenges of drugs for major diseases afflicting developing countries (e.g., AIDS and malaria); and counterfeit products.

Intellectual property abuse and counterfeiting, the fastest growing economic crime, is a $200 to $400 billion global industry. In 2006, the National Association of Boards of Pharmacy (NABP) reported that the prevalence of counterfeit medicines can range to over 10 percent of the drug supply globally. A dramatic growth of global counterfeit and piracy activities would seriously threaten the economic well-being of international pharmaceutical companies.

PHASE DIAGRAMS

Phase diagrams display the characteristics of dynamical systems. They include fixed points (equilibrium points); isoclines, which subdivide the phase space into different vector forces; trajectories, which show particular paths of the system over time; and information on the stability/instability properties of the dynamical system. Phase diagrams have been employed in a number of areas in the social sciences. In economics, for example, they have been used in environmental economics, growth theory, and macroeconomics—most recently in structural macroeconomics. They can be one-dimensional (called a phase line) or two-dimensional, involving a two-dimensional phase space. Phase diagrams can also be used to display discrete systems of difference equations or continuous systems of differential equations—although the latter is the most common.

A deterministic dynamical system has three elements: (1) a set of equations showing the direction of motion; (2) a set of parameters; and (3) a set of initial conditions. Given these elements, the trajectory of the system is defined and can be plotted in a phase diagram. To illustrate these concepts, consider the simple continuous dynamical system in Figure 1.

\[ x(t) = \frac{dx(t)}{dt} = a + bx(t) + cy(t) \]
\[ y(t) = \frac{dy(t)}{dt} = d + ex(t) + fy(t) \]

The initial condition is \( x(0) = x_0 \) and \( y(0) = y_0 \). This system is autonomous since it does not involve time as a separate variable. A nonautonomous system, for example, might have an equation such as \( x(t) = a + bx(t) + cy(t) + h(t) \). This is important because the mathematical properties of dynamical systems apply largely to autonomous systems.

One of the first considerations of a dynamical system is whether it has a fixed point; an equilibrium point. A fixed point for a two-dimensional system is where \( x(t) = x^* \) and \( y(t) = y^* \) for all \( t \). In other words, the system remains at this position. When systems represent economic or social systems, such fixed points identify equilibrium states. They denote a balance of forces and so remain in that position unless something exogenous, such as a shock, disturbs the system. Fixed points are identified by the conditions \( x(t) = 0 \) and \( y(t) = 0 \). In the example in Figure 1, therefore, the equilibrium is where \( x = 6 \) and \( y = 9 \). Because this example is linear, there is only one equilibrium point.

But far more meaning can be given to the equations in the example when they refer to economic or social systems. For example, the first equation may refer to the goods market in a macroeconomic model of the economy, and the second equation may refer to the money market. Each of these markets can be in equilibrium separately or simultaneously. The first is in equilibrium when \( x(t) = 0 \) for all \( t \), while the second is in equilibrium when \( y(t) = 0 \) for all \( t \).

Such conditions for equilibrium in each market separately identify isoclines. Isoclines represent partitions in the phase plane. Each side of the isoclines represents a disequilibrium state. More importantly, each side of the isocline represents vector forces pushing one of the variables in a particular direction. In the example in Figure 1, there are two isoclines. Along the \( x(t) = 0 \) -isocline market, \( x \) is in equilibrium; along the \( y(t) = 0 \) -isocline market, \( y \) is in equilibrium. The system is in total equilibrium when \( x \) and \( y \) are simultaneously in equilibrium. This must be where the two isoclines intersect. Figure 2(a) illustrates this example, and point \( E \) denotes the fixed point of the system. This figure also shows a typical phase diagram in two-dimensional space. The initial point is denoted \( A \). The differential equations indicate the conditions by which \( x \) and \( y \) will increase or decrease over time. But exactly whether \( x \) is increasing (decreasing) or \( y \) is increasing (decreasing) will depend on the sign of \( \frac{dx(t)}{dt} \) and \( \frac{dy(t)}{dt} \) at some time \( t \). For this reason we need to identify the vector forces in each of the quadrants.

The isoclines in this example divide the phase plane into four quadrants (areas). In each quadrant the market for \( x \) (or \( y \) ) is in disequilibrium. When the market is in disequilibrium, it will change over time according to the nature of the differential equations (for continuous systems) or the difference equations (for discrete systems). The vector forces are shown by the arrows in the diagrams. They supply qualitative information about the movement of the system over time. For example, the vector forces in Figure 2(a) show that the system will move in a counterclockwise direction over time. Although the system will move between the vector forces in any quadrant, only a detailed specification of the equations can indicate whether the horizontal force or the vertical force is dominant. With autonomous systems there is only one trajectory through point \( A \), and this is the path \( AE \).

Consider another example illustrating a different application. Europeans discovered the Polynesian civiliza-
tion of Easter Island in 1722 with a population of about three thousand and a set of enormous statues (moai). The island itself was first settled around 400 CE, when there was a large palm forest, although the island was virtually treeless in 1772. The palm was a natural resource used for a variety of purposes, and it sustained the population. However, the island’s rising population, which at its height built the enormous statues, led to deforestation and, along with violent conflict, to the eventual collapse of the Easter Island civilization. Based on information about population and resources, the rise and fall of this civilization has been modeled, and is illustrated in the phase diagram in Figure 3(c) and the time profile in Figure 3(d).

Figure 2: Phase Diagrams

Figure 3: Phase Diagrams

(c) Phase diagram of rise and fall of Easter Island

(d) Time profile for Easter Island

SOURCE: Adapted from Brander and Taylor (1998)
The trajectory illustrates that as the population expanded, the resource base declined, with the population reaching a peak of about ten thousand around 1400 CE. Analytically, we have a stable clockwise spiral. Sociologically, what was so particular about Easter Island? A major characteristic is that the forest involved a slow-growing palm (the Jubea palm), which grew nowhere else in Polynesia. The other Polynesian islands grew the coconut palm and the Fiji fan palm, which have a much shorter fruit-growing age—and none of these islands exhibited the same rise and fall noted on Easter Island.

A feature of dynamical social systems is asymmetric behavior. If, for example, the variable on the x-axis adjusts more quickly than that on the vertical axis, then the system will move in a more horizontal direction in any given quadrant. Another feature illustrated by the vector forces is the possible existence of saddle-path solutions. Systems can generate unstable paths except for a saddle-path, which directs the system to the equilibrium. Such saddle-paths are a particular feature of economic systems that postulate rational expectations. In Example (b) of Figure 2, the saddle-path for the Ramsey growth model denotes a balanced growth path. Saddle-path solutions, however, highlight an unsatisfactory feature of such modeling. There is no reason for the system to initially be on the saddle-path, and if it is not, there needs to be some mechanism to move the system to the one and only path that will take the system to equilibrium. A third feature that dynamical systems highlight is the possibility that systems will follow orbital paths around the equilibrium, never actually moving away from or toward the equilibrium. A major consideration, therefore, of dynamical systems is whether they are stable or not. Many of the features just mentioned, however, are more likely to occur in systems that involve nonlinear inclines, such as the Ramsey growth model.

**PHENOMENAL CONSCIOUSNESS**

**SEE** Consciousness.

**PHENOMENOLOGY**

At the beginning of the twentieth century the philosopher Edmund Husserl (1859–1938) formulated phenomenology both as a philosophical perspective and as a theory of knowledge. It had a great impact on a variety of social sciences. To Husserl, reality is not given, but is constituted. It is thus apprehended in human experience and given meaning and form. Humans look upon their reality as given in a natural and unquestioned way. It is the task of the philosopher to penetrate beyond the taken-for-grantedness of the world of experience (*Lebenswelt*) through a bracketing procedure (*epoché*) in order to arrive at a deeper understanding of the essence of phenomena. For example, the phenomenologist may look at the multiple ways in which humans experience the color red and how they give meaning to it. He or she then has to “bracket” the definitions of red as phenomena or appearances of essential redness.

In his endeavor to establish the basis for an interpretative sociology, Alfred Schutz (1899–1959) critically adopted Max Weber’s insistence that understanding social action was the methodological and epistemological foundation of sociology. However, understanding involved the two perspectives of the actor and observer, and the sociologist most frequently occupies the latter position. Taking Husserl’s notion of the everyday world of experience characterized by the natural attitude of uncritical acceptance, Schutz accounted for social reality as one in which people cognitively suspend doubt. This is the domain of first order constructs. The sociologist, on the other hand, suspends belief in the way Husserl bracketed the world of appearances. This is the domain of second order constructs resulting from sociological reflection. Schutz laid bare the structure of the life world in terms of typifications people make in everyday life along the axes of familiarity and strangeness in space and time. On the basis of these first order constructs the sociologist embarks on the construction of ideal types through a rigorous procedure. Good examples of these ideal typifications can be found.
in his essays titled “The Stranger” (1944) and “The Homecomer” (1945).

Schutz laid the foundations of social constructionism for a wide range of social, cultural, and feminist studies. Widening the perspective beyond the social domain was one of the main contributions of his students, Peter Berger and Thomas Luckmann. In their seminal work The Social Construction of Reality: A Treatise in the Sociology of Knowledge (1966), they positioned phenomenology as a perspective rather than an alternative paradigm in sociology. In their rendering of a sociology of knowledge from a phenomenological perspective, they demonstrate how reality as such, not just social reality, is constructed and installed as objective reality, which in turn affects society’s members subjectively through processes of internalization and socialization. Other social thinkers such as George Psathas adhere to the idea of a phenomenological sociology as an alternative paradigm to functionalism.

Ethnomethodology seeks to problematize the everyday world taken for granted. Its objective is not the interpretation of first order constructs, but exploring how and by what methods people achieve and sustain a sense of order, normality, and morality in their lives. Aaron Cicourel and Harold Garfinkel pioneered this approach. Garfinkel adopted a methodological procedure akin to bracketing through his breaching experiments, during which the investigator acts as a stranger in familiar situations. Society’s members’ reaction to the breaching of social order and rules demonstrate their background expectations about this order and their desire to restore rule-governed situations.

The phenomenological perspective’s focus on the subjective and everyday aspects of human existence proved attractive to investigators from a spectrum of inquiry including medicine, law, architectures, literature, the environment, ethnicity, gender, embodiment, history, and technology. Methodologically phenomenological investigations rely heavily on ethnographies and other qualitative measures.

With its emphasis on reality as a social construct, phenomenologically oriented social science provides fresh insights on local and global issues. Looking at race and racism, for example, it exposes racial orders, in whatever society they occur as historically constructed entities objectified as real. To society’s members it demonstrates how a specific racial order appears cognitively as commonsense and legitimated as natural and how they are made to believe in its inevitability and normality. Finally it throws light on how empowered insiders construct and maintain racial hierarchies and their predominance in them by remaining racially invisible while racializing other groups and assigning them to their “proper place” in society.

Some have criticized phenomenological approaches as conservative due to their preoccupation with the mundane and commonsense aspects of life. This may be true for some studies, but phenomenology’s insistence on a radical critique of knowledge resists any social structure’s self-interested appropriation of social science.

**PHENOTYPE**

Variations in phenotypic characteristics—skin complexion, hair texture, facial features, and stature—play a central role in racial stratification processes throughout the world. Historically, groups that are western European in physical appearance have been privileged over people of color socially, politically, and economically. Within communities of color, individuals who are more European in appearance have been accorded higher status and more opportunities than co-ethnics who are more indigenous in appearance. These overlapping systems of phenotype-based stratification are rooted in the European conquest, colonization, and enslavement of visibly different people from Africa, Asia, and Latin America beginning near the end of the fifteenth century. To justify expansion into these newly discovered lands and the subjugation of their inhabitants, Europeans established boundaries between themselves and others based on phenotype and constructed ideologies supporting their own cultural superiority. White, European appearance became equated with civilization, beauty, and competence, while indigenous appearance became equated with savagery, ugliness, and incompetence. Miscegenation resulted in a continuum of phenotypic types in these societies, and this ideological framework sometimes supported more a privileged treatment of mixed-raced subordinates. Structural and social-
psychological consequences of phenotypic hierarchies are still evident to varying degrees in communities of color in the Americas and in other parts of the world.

PHENOTYPE AND STATUS ATTAINMENT

At the structural level, there is a strong link between phenotypic appearance and status attainment, which has been studied most systematically in the Americas. In the United States, where the rule of hypodescent declared that an individual with any degree of African ancestry was black, the burden of blackness has not been equally shared. It is widely held, although not uncontested, that African American slaves and free persons of color with visible white ancestry had greater access to material goods, education, and cultural capital and, consequently, emerged as social and economic elites within African American communities after emancipation in the mid-1800s. More contemporary analyses of longitudinal and cross-sectional data show that lighter skin, which is usually associated with other Eurocentric facial features, is positively correlated with education, employment, occupational prestige, and income among African Americans. Indeed, some research suggests that educational and occupational differences between the darkest and lightest African Americans are nearly equal to the differences between whites and African Americans. A study published in 2006 suggested that the advantage of light skin disappeared for African American cohorts born in the mid-1940s, but it is not clear if these analyses included adequate controls for sample attrition where African Americans with darker skin and a lower socioeconomic status may have been lost to the study due to higher mortality. Thus, the most convincing evidence to date is that phenotype continues to matter for African Americans.

The link between phenotype and socioeconomic status is also evident within the Mexican-origin population in the United States and Mexico. The conquest of Mexico by the Spaniards resulted in a caste-based society that placed light-skinned, European-looking persons at the top of the social and economic hierarchy, the darker native inhabitants of Mesoamerica at the bottom, and the mestizos or persons of mixed race in an intermediate position. As a consequence of racial intermixture during the colonial era, phenotype in the contemporary Mexican-origin population ranges on a continuum from those who appear white to those who have dark skin, indigenous facial features, and shorter height than average. In contemporary Mexico and the United States, anecdotal and rigorous empirical analyses show that Mexican-origin persons with more indigenous complexions and appearance have lower levels of educational attainment, lower occupational status, and lower incomes.

Brazil has long touted that it is a racial democracy where social, economic, and political inequalities are present but are not based on race. Unlike the United States, Brazil did not implement legal segregation, and its racial ideology encouraged racial mixing with the latter resulting in a tri-racial system consisting of whites, browns, and blacks. Yet, in spite of its “alleged” tolerance for racial differences and a fluid racial classification system, phenotypic appearance is an important determinant of Brazilian life chances. As carefully documented by Edward Telles in Race in Another America: The Significance of Skin Color in Brazil (2004), brown and black Brazilians are disadvantaged on all socioeconomic indicators relative to whites, and the gap between browns and blacks is quite small. He reports that even among siblings in multi-phenotypic households, those who are white are less likely to drop out of school than those who are darker. Similar to other Latin American countries, limited social mobility of mixed raced individuals blunts recognition of phenotype-based inequality. Collectively, the research on status attainment in the United States and Latin America argues that phenotypic discrimination is widespread throughout the Americas. The closer individuals of color resemble white institutional gatekeepers, the more comfortable their material lives are likely to be on average.

Interestingly, a growing mixed race population in the United States, along with other factors, suggests that the U.S. racial stratification system is moving closer to the Latin American model where an intermediate group will serve to buffer racial conflict between whites at the top and black Americans and other “symbolically” black groups positioned at the bottom of the race hierarchy. This idea is buttressed by widespread adherence to a color-blind discourse and a fluid racial classification system that mistakenly asserts that racism is no longer a problem in the United States. A tri-racial system does not mean the end of racism, but it does mean that phenotype is likely to become even more important in racial dynamics.

PHENOTYPE AND SOCIAL-PSYCHOLOGICAL PROCESSES

The phenotypic-based reward structure imposed by racially dominant elites has also affected social-psychological processes internal to communities of color. Phenotypic evaluations and biases are embedded in ethnic identity, complexion preferences, and concepts of beauty. Latin Americans in the United States tend to eschew black identity in favor of white identity even when their complexions are dark and their country of origin has a high proportion of Afro Latinos and Afro Latinas. Some research indicates that in countries like Brazil, great pains are taken to avoid or hide African ancestry. Thus, despite claims that racism does not exist in Latin America, it is
clear that blackness and indigenous appearance are devalued. Preference for white or lighter skin is found in many communities of color. Among African Americans, there are indications that uniform preference for very light skin has diminished, but very black skin is not especially desired. Preferences for light skin have also been documented in Asian countries, in the Asian Diaspora, and among Americans of Mexican origin.

Among all people of color, phenotypic preferences disproportionately impact women because they define who is physically attractive, and expectations of attractiveness are applied more stringently to women than men. In many societies around the world, idealized beauty and femininity are constructed to incorporate white or light skin, long hair, thin bodies, and European facial features. Women whose phenotype places them at a distance from this ideal sometimes turn to cosmetic enhancements. African American women, for example, straighten their hair, wear colored contact lenses, and have attempted to become lighter by bleaching their skin. Modern skin bleaches often contain harsh chemicals that cause severe skin damage, and despite substantial health risks and attempts to ban them, bleaching products are a major problem in African countries and the West Indies. In Asian countries, women are bombarded with ads for facial creams that promise to lighten and brighten. Cosmetic surgeries, marketed under the guise of enhancing one’s ethnicity, are increasing among women of color in the United States, but these procedures seem to erase rather than enhance ethnic phenotype. Women engage in these practices because attractiveness operates as a form of social capital that translates into economic rewards such as access to employment and upward mobility through marriage. In some South Asian groups light skin complexion is referenced in ads for prospective spouses, and among the Kerala of India light skin can be important in dowry negotiations. Light-skinned African American women also tend to marry more economically successful males than their darker-skinned sisters. For women, looking good counts, and looking good is heavily influenced by Eurocentric facial features and light complexion.

A CONTINUING FACTOR
Phenotypic appearance is the basis for racialized processes that privilege some groups over others and some individuals within groups. As nations become more racially and ethnically diverse and European cultural and aesthetic forms are exported around the world, it is likely that phenotype will continue to shape human interactions.

PHILANTHROPY
The word *philanthropy* derives from the Greek word *philanthrōpos*, meaning “love of mankind.” In more conventional terms, it is the act of giving money to charitable causes. Although among western cultures giving has its roots in Judeo-Christian notions of tithing, or contributing to one’s church, philanthropy has also been linked to capitalism.

Philanthropy has become a cultural norm in the United States. Americans give their money at a higher rate than any other country in the world. Approximately 2 percent of the U.S. gross domestic product (GDP) is given to nonprofits (Gaudiani 2003). Although corporations and foundations practice philanthropy, the real power of American giving lies with individuals. According to the Association of Fundraising Professionals (2003), individual gifts represented approximately 76 percent of the money raised by U.S. nonprofits in 2002.

Philanthropy is seen by some as a supplement to government, and by others as a way to effect change without involving government. Much of the funding for religious, artistic, educational, and health-related causes comes from
Philanthropy

philanthropic sources. In fact, many cultural, religious, and artistic organizations are almost entirely dependent on philanthropic donations. The government gives these organizations tax-exempt status in the United States. Scholars of philanthropy have identified these nonprofit organizations as the "third sector," as they are neither public nor private in nature (Payton 1991).

Throughout history there have been many critics of philanthropy. On a theoretical level, Marxists have argued that philanthropy is another aspect of capitalism that serves the interests of the rich; on an empirical one, social scientists such as C. Wright Mills showed how a small group of families control the wealth in capitalist nations, and any notion of creating social mobility through philanthropic assistance may be a mere illusion. More recently, scholars have considered race as a factor in philanthropic issues of control (Anderson 1988; Watkins 2001). In this regard there are many examples of philanthropists exerting pressure on recipients of their gifts. The oil tycoon John D. Rockefeller Sr. often tied rigid stipulations to his donations, especially those given to African American education. According to historian James D. Anderson (1988), during the late nineteenth and early twentieth centuries Rockefeller and his associates funded only vocational and manual arts education for blacks, while supporting the liberal arts for whites. Philanthropists such as the steel magnate Andrew Carnegie and Sears and Roebuck founder Julius Rosenwald followed Rockefeller's lead (Anderson 1988; Watkins 2001). In addition to their philanthropic efforts in the United States, the Carnegie, Rockefeller, and Ford foundations participated (and continue to participate) in extensive overseas initiatives, including school building in many African countries, health-related efforts in South America, and housing and agricultural programs throughout Africa, Asia, and South America. Many have questioned whether these efforts truly help the recipient nations, or merely serve the interests of U.S. foreign policy and global capitalism. On occasion, foundations have been publicly criticized for the projects that they fund both in the United States and abroad. For example, in 2003 the Jewish Telegraphic Association, a New York wire service, accused the Ford Foundation of funding organizations that supported anti-Semitic behavior. Initially, Ford denied the allegations, but the sometimes controversial foundation later learned that some of their grantees were, in fact, promoting anti-Semitic attitudes. This realization forced the foundation to make policy changes and caused discontent in the foundation world as these nonprofits worried about government interference in their grant making.

Over the course of U.S. history some have felt that the nation must choose between government-controlled and private solutions to social problems. This perspective was especially prevalent during the Roosevelt administration. Angered by Franklin D. Roosevelt's New Deal policies, many of the country's wealthy individuals refused to give because they felt the government had taken over the domain of philanthropy—a domain that they believed was rightfully theirs (Cutlip 1965). Some factions continue to hold this view today. However, most philanthropists see their gifts as a supplement to the support that government provides.

According to the conventional view, a philanthropist is a wealthy person who gives to those with less. Yet this definition tends to obscure acts of giving by middle- and lower-income people; moreover, it depicts philanthropy as primarily a white male enterprise. In response, some scholars, including Andrea Walton (2005), Emmett D. Carson (1993), Kathleen McCarty (1991), and Marybeth Gasman and Katherine Sedgwick (2005), have expanded the definition to include the giving of small monetary sums, time, and goods. Under this new definition, American philanthropists include the very wealthiest (e.g., Andrew Carnegie, George Eastman, Bill Gates, and John D. Rockefeller) and those with barely enough to make ends meet. In fact, individuals in the lowest income brackets tend to donate as much or more than their higher-waged counterparts as a percentage of their income. And in this view, minorities and women are as much philanthropists as white men. For example, a survey conducted by the Chronicle of Philanthropy in 2003 found that African Americans in particular give 25 percent more of their discretionary income to charity than whites (Anft and Lipman 2003).

The March of Dimes is an excellent example of the power of collective and small donors. From 1938 to 1954, 4 billion dimes, many of them collected at a time from all sectors of the U.S. population, paved the way toward a cure for polio. Another example of vast philanthropic giving from small donors can be seen in the black churches, where parishioners, often nearly destitute themselves, donate more than 10 percent of their income. In recent times, the tragedy of September 11, 2001 spurred renewed interest in philanthropy among ordinary Americans. Besides the $2.9 billion in monetary contributions that citizens gave in the wake of the disaster, there were enormous in-kind contributions as well. For example, in the initial days after the tragedy, more than 500,000 people donated blood at American Red Cross centers across the fifty states, even after blood supplies were deemed adequate.

An innovative form of philanthropy that has emerged from the newest generation of American entrepreneurs and capitalists is venture, or "high-engagement" philanthropy. In this approach, the donor is engaged beyond providing financial support to the nonprofit organization. Venture philanthropists often require their grantees to
craft, with their assistance, strategic and long-term plans, find other sources of funding, and create new partnerships. As it is a recent development, few scholars have been able to assess venture philanthropy’s effectiveness and value. However, some skeptics have likened this “new” form of philanthropy to that of the turn-of-the-century industrial philanthropists—large sums of money accompanied by large amounts of interference.

**PHILLIPS, A. W. H.**

1914–1975

Alban William Housego (“Bill”) Phillips was born in New Zealand in 1914. Reflecting a boyhood interest in electronics, he became an electrical engineering apprentice and then wandered through Australia and Russia during the Great Depression years. He continued to study for the Institution of Electrical Engineers examinations by correspondence, and passed the examinations in 1938. During World War II (1939–1945) he served in the Royal Air Force in Asia, where he was captured and imprisoned. His experiences in the prison camp led him to study sociology at the London School of Economics after the war. One of the required units was economics, which led to an interest in macroeconomics.

Keynesian economics, which required the study of a complete system, was then coming to the fore. Phillips recognized that there were similarities between the systems studied by engineers and those by economists. Because economists were unfamiliar with systems, he recognized the utility of having a visual demonstration of the response of a miniature economic system after it was disturbed by a shock, and of how this response might be modified. Consequently, he built a hydraulic model of an idealized economy—the “Phillips machine.” This was initially done for Leeds University, but improved models were later constructed for a number of universities around the globe. The machine was a great success, influencing many researchers, including Nobel Laureate James Meade (1907–1995). Today, simulations on digital computers have replaced the Phillips machine, but the ideas underlying it appeared in a number of Phillips’s classic papers. These emphasized the difficulties that could arise when attempts were made to control an economic system, since economic policy actions often take a long time to have an effect upon targets. In these papers, Phillips studied the performance of an economic system when policy was envisaged as being set in a (then) novel way—according to a set of rules.

After this early work, Phillips’s research focused upon examining relationships in the economic system and propounding methods for estimating the parameters that characterize them. His best-known paper determined a relation between inflation and the rate of unemployment that became known as the Phillips curve. The original curve linked the rate of wage inflation with the unemployment rate. It was transmuted into a relationship between price inflation and unemployment, particularly by Solow and Samuelson in the 1960s.

Phillips was appointed lecturer to the London School of Economics in the 1950s and rapidly rose to the position of Tooke Professor. In 1967 he moved to the Australian National University in Canberra but within a few years he suffered a stroke. Retiring to Auckland, New Zealand, he died in 1975. That Phillips’s ideas have had an enduring legacy is apparent from the structure of a very popular model used for policy discussion in central banks—the new Keynesian policy model. Two of the three
equations in its closed-economy variant are a Phillips curve and an interest-rate rule for describing how interest rates are set in response to inflation and excess demand.

---

**PHILLIPS CURVE**

The term *Phillips curve* originated in the work of New Zealand–born economist A. W. Phillips (1914–1975). In a 1958 article, Phillips plotted annual observations on wage change against unemployment in the United Kingdom for the 1861–1957 period, and he fitted a nonlinear curve by trial and error to the six grouped observations on wage change and unemployment (using an unusual technique, as noted by Desai [1975]). The resulting equation of $w = -0.900 + 9.638U^{-1.394}$, where $w$ is the (annual) rate of change of money wages and $U$ is the unemployment rate, displays the negative relationship between wage change and unemployment. The equation also places a floor under money-wage annual change of −0.9 percent.

The term *Phillips curve* has subsequently been used in a variety of ways and to invoke a number of mechanisms. Paul Samuelson and Robert M. Solow (1960) converted the curve into a relationship between price inflation and unemployment by deducting the presumed rate of growth of productivity from growth of wages to provide a presumed growth of prices. Later, there was an appeal to the links between output and unemployment to derive an equation linking price inflation and output (or capacity utilization or output gap).

Precursors can be found: For example, Irving Fisher’s 1926 article “A Statistical Relation between Unemployment and Price Changes” was reprinted in 1973 under the heading “I Discovered the Phillips Curve.” Fisher argued that “surprises” in inflation (i.e., unanticipated inflation) lead to supply responses, with the postulated positive effect of unanticipated inflation on economic activity. Anthony Thirlwall (1972) argues that Arthur Brown (1955) has a strong claim to the discovery of an empirical relationship between wage changes and unemployment. His diagram (Brown 1955, p. 199) maps out the wage change–unemployment observations for the United Kingdom from 1880 to 1914. Even earlier, Karl Marx (1818–1883) argued that the industrial reserve army of the unemployed regulated the movement of wages.

Richard Lipsey (1960) provided a theoretical justification for the Phillips curve on the basis of a labor-market adjustment process whereby wages change in response to the level of excess demand for labor, and unemployment is viewed as a (negative) proxy for excess demand for labor. Milton Friedman argued that “Phillips’ analysis of the relation between unemployment and wage change … contained a basic defect—the failure to distinguish between nominal and real wages” (1968, p. 8). This observation led to the expectations-augmented Phillips curve, such as $w = p + f(U - Un)$ (abstracting from the general trend upward of real wages), where $p$ is the expected rate of inflation and $Un$ is the “natural rate of unemployment,” with the significant property that money wages would rise in line with expected inflation when $U = Un$. When unemployment was below this “natural rate,” then wages would rise faster than prices, and inflation overall tends to rise. The “natural rate” was viewed as “the level that would be ground out by the Walrasian system of general equilibrium equations, provided there is embedded in them the actual structural characteristics of the labor and commodity markers, including market imperfections, stochastic variability in demands and supplies, the cost of gathering information about job vacancies and labor availabilities, the costs of mobility, and so on” (Friedman 1968, p. 8).

Edmund Phelps introduced “a sort of Phillips Curve in terms of the rate of price change, rather than wage change, that shifts one-for-one with variations in the expected rate of inflation” (1967, p. 254) with “the rate of inflation depend[ing] upon the utilization ratio and upon the expected rate of inflation” (p. 261). Using the idea that expectations were adaptive, Phelps developed the idea of a vertical long-run relationship between inflation and output, with output at the level determined by the “equilibrium utilization ratio.”

Expressing the argument in terms of wage changes and unemployment, in the short-run, with a given state of expectations, there is a trade-off between wage change and unemployment. But expectations will adjust to (or even anticipate) the experience of wage inflation (and the subsequent price inflation). When expected price inflation fully incorporates wage inflation, then $p_e = p = w$, and hence $f(U - Un) = 0$: This became known as the *vertical long-run Phillips curve*. This has enormous policy implications: The economy has to operate at the “natural rate” if
continuously rising or falling inflation is to be avoided. Specifically, unemployment below the “natural rate” would see escalating inflation, leading to hyperinflation.

Many of the arguments developed by Friedman were anticipated by David Champernowne. Champernowne concluded that “no period of monetary employment or of monetary unemployment is likely to last for very long. We expect there to be alternate periods of monetary employment and of monetary unemployment, so that the actual level of unemployment would oscillate above and below the level of basic unemployment” (1936, p. 206), where “basic unemployment is the amount of unemployment that there would be in that situation if each man demanded neither more nor less than his basic real wage” (p. 203). But a significant difference was that Champernowne postulated responses from the monetary authorities through interest rates as the mechanism by which actual unemployment moved to the level of “basic unemployment.”

INFLATION AND THE OUTPUT GAP

The term Phillips curve is now widely used to signify the relationship between price inflation, expected price inflation, and the output gap, which feature heavily in the new consensus macroeconomics (e.g., Meyer 2001; Woodford 2003). The new Keynesian approach to the Phillips curve is based on price decisions being forward looking, and at the level of the individual firm price decisions depend on the expectations of prices to be charged by other firms in the future. But price decisions are staggered (following Calvo 1983), and only a proportion of firms change their price in any given period. Each firm is postulated to produce a differentiated product, and faces a constant price elasticity of demand curve for its product. In each period, a proportion of firms change price (but others do not). In each period, the probability that a firm changes price is \( \alpha \), which is independent of any change of price in the preceding period. The aggregate price level is then a weighted average of the lagged price level and the optimal price (derived from forward-looking profit maximization) set by those changing price. These considerations yield an equation involving prices and marginal costs: A typical form would be (from Galí and Gertler [1999], equation 3): \( p_t = \lambda p_{t-1} + \beta E_t [p_{t+1}] \), where \( mc \) is real marginal costs, \( \beta \) is the subjective discount factor, and \( \lambda \) depends on the frequency of price adjustments and \( \beta \). Some approximations and the assumption that marginal cost is positively related with output yield an equation of the form: \( p_t = \lambda \kappa x_t + \beta E_t [x_{t+1}] \), where \( \kappa \) is the output elasticity of marginal cost, and \( x \) is the output gap.

EVIDENCE

The origins of the Phillips curve were empirical rather than theoretical. Throughout its history, there have been claims and counterclaims on the extent of the empirical support for the Phillips curve, and on its disappearance and reappearance. The initial proposition from the Phillips curve literature was a negative relationship between wage changes and unemployment. This was augmented by a proposition that the coefficient on expected price inflation was unity and there was a “natural rate of unemployment” consistent with constant inflation. Although the “natural rate” has often been treated as a constant, it can rather be seen, reflecting the quote from Friedman above, as influenced by a range of supply-side factors, but viewed as independent from the course of the level of aggregate demand or economic activity.

Although the Phillips curve as a single equation features in much theoretical literature, the empirical approach generally draws on a two (or more) equation approach involving both wage and price determination. This entry limits its discussion to the single-equation approach of a Phillips curve. The differences in the empirical results are reflected by the following. Robert Gordon (1997) considered a basic model (for the United States) in which inflation is regressed on lagged inflation, current and lagged “demand” (unemployment gap, output gap), change in productivity, in relative import price, and in relative price of food and energy (and Nixon incomes policy on/off). Gordon tried three alternative price indices. He reports that “estimated sums of coefficients on the inflation inertia variable are very close to unity, while those on the unemployment gap are always highly significant and of the correct sign. The significance of the various supply variables differs, but with two exceptions of insignificant coefficients, they all have the correct sign” (Gordon 1997, p. 24). “Taken as a group, the inclusion of the supply side variables makes a substantial difference, especially during the 1973–1981 period, which is influenced by adverse supply shocks” (p. 25). The sum of coefficients on lagged inflation is 1.01 (but 24 lags on quarterly basis) and on the unemployment gap the sum is −0.61 (current plus four lags).

In contrast, Robert Eisner separated out the effects of high and low unemployment and found “great disparities in the relations involving high and low unemployment” (1996, p. 118). For example, he found that unemployment had a negative impact on inflation when unemployment was high, but a positive effect when unemployment was low. Furthermore, the coefficients on lagged inflation were below unity when unemployment was low. Overall, Eisner concluded that “there may indeed be no stable universal relation among unemployment and all the various factors that may contribute to inflation, let alone accelerating inflation” (1996, p. 128).

For the new Keynesian Phillips curve, N. Gregory Mankiw argued that it “has many virtues, [but] it also has
Phillis Curve

one striking vice: It is completely at odds with the facts” (2001, p. C52). In a similar vein, “attractive though the need to establish a direct inflation-output link may be, as an empirical framework for explaining inflation over the business cycle, the New Keynesian Phillips Curve … in inflation-output space has not been particularly successful” (Chadha and Nolan 2004, p. 271). Jordi Gali and Mark Gertler noted that “it is often difficult to detect a statistically significant effect of real activity on inflation using the structural formulation implied by the theory, when the measure of real activity is an output gap (i.e., real output relative to some measure of potential output). Failure to find a significant short-run link between real activity and inflation is unsettling for the basic story” (1999, p. 196; see also Gali et al. 2005).

The experience since the beginning of the 1990s, at least in the United States and the United Kingdom, could be characterized by a rather stable rate of inflation as unemployment declined substantially (at least until 2001), which some have described as akin to a horizontal (rather than a vertical) Phillips curve.

The shifts in estimates of the “natural rate of unemployment” were illustrated by Stephen Nickell (1990), who estimated the equilibrium rate of unemployment in the United Kingdom as having risen as follows (with actual rates of unemployment given in parenthesis):

- 1956–1959: 2.2 percent (2.24 percent)
- 1960–1968: 2.5 percent (2.62 percent)
- 1969–1973: 3.6 percent (3.39 percent)
- 1974–1980: 7.3 percent (5.23 percent)
- 1981–1987: 8.7 percent (11.11 percent)
- 1988–1990: 8.7 percent (7.27 percent)

Richard Layard, Nickell, and Richard Jackman (1991, p. 436) report actual and equilibrium unemployment for nineteen countries for each of three decades, and an essentially similar pattern is provided—namely, the two types of unemployment move together. Olivier Blanchard remarks that “the natural rate is at best a weak attractor” and that “the natural rate is often as much an attractee as it is an attractor” (1995, p. xiii). The “natural rate of unemployment” is seen to vary over time, but that leaves open the question of why it does so.

BIBLIOGRAPHY

PHILOSOPHY

Philosophy is the systematic inquiry into fundamental questions about the nature of reality, knowledge, and behavior. As an academic discipline, philosophy has three central areas of inquiry and a number of other related subdisciplines that follow from these three areas. The three core areas are metaphysics, epistemology, and ethics. Other important branches of philosophy include logic, the philosophy of science, the philosophy of mind, the philosophy of language, aesthetics, political philosophy, and the philosophy of religion. Each of these areas can be further broken down into subspecialties; so for instance, the philosophy of science includes the philosophy of physics, the philosophy of biology, the philosophy of math, the philosophy of the social sciences, and so on. Furthermore, given what is generally taken to be the systematic nature of philosophical inquiry, the boundaries between the different areas of study and how each area relates to others are themselves matters of some disagreement. Is the philosophy of science to be regarded as a subdiscipline of epistemology or as a separate area of study? What is the relation of the philosophy of mind to metaphysics, on the one hand, and to the philosophy of psychology, on the other? What is the relation of political philosophy to ethics and to the philosophy of law, and should all of these areas be considered subdisciplines under a broader rubric such as value theory? Indeed, most philosophers would agree that the question “what is philosophy?” is itself a philosophical issue about which there is no one accepted answer, regardless of whether philosophy is taken as a method of inquiry, a way of understanding and living in the world, or as an academic discipline.

THE FUNDAMENTAL QUESTIONS OF PHILOSOPHY

Perhaps, then, a better way of characterizing philosophy is in terms of the fundamental questions that concern the three core areas. Metaphysics traditionally asks questions about the fundamental nature of reality. What really exists? What are the fundamental constituents of reality? Are there two (or more) fundamental and mutually irreducible substances, for instance, mind and matter? What is the nature of identity, of causation, and of time? How should we characterize the difference between persons and bodies? Metaphysical questions cross over into what might seem to be other areas of philosophy. For instance, the question of the existence of God is a metaphysical question that is at the heart of the philosophy of religion. Likewise, the metaphysical question of the relation of mind and body has traditionally been the central focus of the philosophy of mind. One might regard questions about the nature of truth as metaphysical, but the nature of truth is a central concern in both the philosophy of language and logic. The problems of freedom and determinism and the nature of freedom are generally taken to fall within metaphysics, but they have obvious and important implications for ethics, political philosophy, and the philosophy of law.

Epistemology is the study of knowledge, what it is, and how we acquire it. What can we know? What are the limits of knowledge? Can we really know anything? Or is skepticism of some variety true? If we cannot know anything, if genuine knowledge (in a particular domain or in general) is impossible for humans, then some sort of skepticism must be the case. The traditional challenge of the skeptic going back at least as far as Plato is to the assertion that we are justified in claiming to know something (in particular or in general as the case may be), the claim to have secure knowledge. So the options, in a crude and simplified way, are between having secure knowledge or skepticism. What is the difference between mere belief and knowledge? Is true belief the same as knowledge? Is there a fundamental difference between empirical knowledge and knowledge of a priori entities such as concepts and numbers? Questions about the nature of justification and how we acquire it, as opposed to mere opinion, also are part of epistemology.

Some questions are both epistemological and metaphysical. Such questions often have to do with the nature of perception. For example, the question of the relation of appearance to reality, that is, of how the world appears to us versus how it really is in itself, is at once both a question in epistemology (what we can know of how the world really is) and metaphysics (the nature of the real). Hovering over these epistemological concerns are questions about rationality and what it means to be, think, and act rationally. The concept of rationality might be taken to be in part epistemological and in part metaphysical, but it also is important in normative domains such as ethics and in logic.
Philosophy

Ethics, or moral philosophy, has three traditional questions at its core: How should one live? What is the good? What is the right? These questions have to do with, in turn, the nature of virtue, value, and duty or right action. One can approach ethics, as the Greeks typically did, by thinking about the first question: how a person should live. What is the proper or best life for a human being? What kind of person should I be? What kind of virtues or disposition of character should I attempt to cultivate in myself? Answering these questions allows one to determine what is good (what adds value to a life) and what is right (what duties one has and how one should act in certain situations).

In the modern period, philosophers have typically started with one of the other questions and moved from it to the other two concerns. One approach, consequentialism including utilitarianism, starts with a theory of the good or what has value, and then determines right action in terms of what will bring the most good into the world. Virtues are understood as those character traits that will help one best promote the good. The other major approach, often called deontology, starts with a theory of duty or right action. Certain actions are taken to be dutiful or right because of some feature they possess. The good is understood in terms of the promotion of such actions, or if there is an independent theory of the good, the promoting the good is seen as subservient to doing one’s duty. A third contemporary approach, virtue theory or neo-Aristotelianism, attempts to revive the approach of the Greeks and make virtue the fundamental normative concept.

These questions are all considered part of normative ethics, or the theory of how one should act. When these sorts of questions are asked of specific sorts of cases or problems, normative ethics shades into applied ethics, which includes a number of subfields such as medical ethics or bioethics, environmental ethics, and business ethics. Another important area of ethical inquiry is metaethics, or the theory of the nature of ethics. Metaethics is the inquiry into metaphysical and epistemological issues about normative ethics and the nature of moral language. Metaethical issues include questions about the nature of value and truth in ethics; epistemological issues about ethical judgments such as whether ethical assertions admit of truth, how we can come to have knowledge in ethics, and the nature of justification in ethics; and philosophy of language concerns about the nature of specifically moral language such as the moral ought and good.

The discipline of philosophy as practiced in the English-speaking world and most of Europe is primarily the tradition of the West starting with the Greeks. Non-Western traditions, including Chinese philosophy, Indian philosophy, African philosophy, and Islamic philosophy, receive some attention but remain largely on the margins of the field. In the twentieth century, a major and rather complicated division developed in European philosophy between two schools or approaches to the subject generally known as Analytic philosophy and Continental philosophy. Both approaches share the same history of the discipline, but with somewhat different readings of certain figures such as Immanuel Kant until at least Georg Wilhelm Friedrich Hegel. The Analytic tradition sees its specific roots in Gottlob Frege, Bertrand Russell, G. E. Moore, and Ludwig Wittgenstein in the early twentieth century, whereas the Continental tradition traces its origins to such figures as Franz Brentano, Edmund Husserl, Friedrich Nietzsche, and Martin Heidegger. The Continental tradition includes such philosophical sub-disciplines as phenomenology, existentialism, and postmodernism. By the middle of the twentieth century the Analytic approach was dominant in Anglo-American philosophy, and the Continental approach held sway in France, Germany, and most of Western Europe.

Unlike many disciplines, in particular the natural sciences, the history of philosophy is itself an important field within philosophy. Although the history of physics might be of some interest to physicists, most would not consider it an important field of current research or inquiry within physics. Philosophers, however, regard some mastery of the history of their discipline as an essential part of current work in most areas of philosophy. More than in most other subjects, philosophers recognize that how one tells the history of the field often affects how one understands the very nature of the problems that seem of greatest contemporary interest. Discussions of the major figures in the history of Western philosophy such as Plato, Aristotle, René Descartes, David Hume, Kant, and John Stuart Mill are directly relevant to current work in ethics, epistemology, and many areas of metaphysics so much so that positions in current debates are often labeled as Kantian or Humean or Cartesian.

THE RELEVANCE OF PHILOSOPHY TO THE SOCIAL SCIENCES

Historically, the social sciences have either been offshoots of philosophy or very closely connected to philosophical discussions. In some sense the social sciences have their roots, as do the natural sciences, in Greek thought. Plato and Aristotle can lay claim to being the first political scientists and economists. Not until the modern period, however, starting with seventeenth-century figures such as Thomas Hobbes and Giambattista Vico, did the social sciences begin to emerge in their modern form. Still, it was only in the late eighteenth century and into the nineteenth century that thinking about the nature of society
and social behavior began to be seen as an area of investigation separable from thinking about the deep normative issues of ethics and political philosophy. The great figures regarded as among the fathers of modern social science such as Adam Smith, Karl Marx, Émile Durkheim, Max Weber, and William James were all trained in philosophy. Only in the twentieth century, largely as a result of the influence of positivism and the specialization of the academy, did a split between the investigation of the nature of social life and processes and the traditional concerns of philosophy clearly emerge.

A subdiscipline of contemporary philosophy of particular relevance to the social sciences is the philosophy of the social sciences. A central question of this subdiscipline concerns how to situate the social sciences in relation to the other disciplines. To what degree should the social sciences on the model of the natural sciences, such as physics, be understood? Or should they rather be viewed as closer to the humanities? Or should the social sciences be regarded as different in important respects from both the natural sciences and the humanities? Part of the difficulty in answering this question is that the social sciences span a broad spectrum of types and areas of investigation, from the study of the mind and individual behavior in different arenas of social existence such as the economic or political, to understanding alien cultures, to social and political theory on the broadest scale. Can one expect to find epistemological, metaphysical, or methodological unity across all areas of investigation that are generally regarded as social sciences?

Still, there are central questions that remain at the core of philosophical interest in the social sciences. Since the Greeks, philosophers have speculated about whether society and the institutional norms and rules that govern human life are natural or the result of convention. Thinking about this question leads naturally into questions about diverse cultures and to epistemological and methodological issues concerning how one understands alien cultures. These questions about the nature of foreign cultures and the possibility of our understanding cultures different from our own are central to anthropology and the philosophy of anthropology, a subfield of the philosophy of the social sciences.

A different, but related, epistemological issue concerns how we explain social behavior. The standard model of explanation in the natural sciences is causal explanation. This model assumes that there are lawlike generalizations in terms of which we can understand particular occurrences or phenomena. But are there comparable laws or generalizations in the social sciences, especially that hold across cultures? Many doubt that there are. Alternatively, some have tried to attempt to explain social phenomena in terms of functional explanation, where the explanation appears to be in terms of the effects brought about rather than the causes of those effects. There are, however, serious questions about the relation of causal and functional explanation. A third important position holds that neither causal nor functional explanation is appropriate in the social sciences. Rather, the goal of the social sciences is understanding in the sense of the recovery of the meaning of individual or social behavior and phenomena from the point of view of the agents themselves. This debate has traditionally been referred to as that between Eklaren (explanation) and Verstehen (understanding).

Another central debate in the philosophy of the social sciences concerns the relation of social structures, institutions, and practices on the one hand, and individual behavior and meaning on the other. Can all social phenomena be reduced to the aggregation of individual behaviors and meanings, in which case the goal of the social sciences should be to explain everything on the level of the individual? Or is the social ultimately irreducible to the level of the individual? In the latter case, the social sciences, or at least some of them, seem to occupy a conceptual space separate from the natural sciences, psychology, and the humanities. The position that holds that reduction of the social to the individual is possible and epistemologically required can be called methodological individualism. The position that resists this reduction and holds for a separate conceptual space for the social can, accordingly, be referred to as methodological holism.

One final and important issue should be mentioned: the relation of fact and value in the social sciences. The natural sciences are concerned with facts, the facts out of which the world is constructed, and regard themselves and are generally regarded as value neutral. The relation of fact and value is much more problematic in the social sciences in at least two ways. Although natural science can be used in ways that might be judged good or bad, social scientists more often seem to bring value judgments and commitments to their work, making it harder to separate purely scientific judgments from value judgments. On a more basic philosophical level, there is a question about whether the very subject matter of the social sciences can be constituted independently of values. Although some hold that all theory, regardless of whether it is in the natural or social sciences, is value-laden, those in the natural sciences have traditionally thought of themselves as concerned with a realm of fact independent of values. Whether there are social facts with anything similar to the same degree of value independence has long been and remains a much more controversial claim. The constitution of social facts may inescapably involve normative assumptions, in which case the object domain of the social sciences would be significantly different from that of the natural sciences.
PHILOSOPHY, MORAL

Moral philosophy is roughly the same as ethical philosophy—morals and ethics are virtually indistinguishable, moral being Cicero’s translation of the Greek term ethics or ethos, which meant the customs and manners characteristic of a country or city-state. Typically, one distinguishes the concrete level of moral behavior and judgments from a higher theoretical level where one reflects upon this concrete level and proposes higher-order ethical principles about ethical behavior and judgment (ethical theory).

Moral philosophy is ordinarily divided into three levels: applied ethics, normative ethics, and meta-ethics. Normative ethics is primarily concerned with two questions: (1) What actions should an individual perform? and (2) what states, properties, things, and persons are (morally) good or valuable? Ordinarily, a normative ethicist will propose answers to these questions in terms of normative principles—principles specifying what one ought to do. Applied ethics is concerned with the application of these normative principles to concrete areas such as social science ethics. Meta-ethics is concerned with the theory of normative ethics: Are ethical propositions true or false? What is the meaning of moral terms? What kind of reasoning can be advanced in support of ethical arguments? In the twentieth century meta-ethics dominated the field until midcentury, when normative theory made a gallant return. Since then all three areas have been actively pursued. The present discussion will be limited to normative ethics.

INTRODUCTION

Beginning with Socrates and Plato, philosophers have been concerned with the question of the nature of the good life and how one should attain it. It was the characteristic Greek view that an individual could reach this ultimate goal only as part of a larger social entity—the polis—of which he was an integral part. There was, therefore, little if any conflict between the individual’s real interests and the welfare of the larger community. In short, as Plato argued in The Republic, it pays to be moral because an individual can be happy in life, and thus attain the ultimate state of well-being, only if the individual has the property of justice. This view was characteristically Greek, and widely shared among Greek thinkers. For example, the Stoics believed that a concern for the well-being of all human beings was developmentally built into human nature, and that even though humans begin their lives as self-centered animals, they mature to the point where they are (and should be) concerned about all humankind; this constitutes natural law theory.

Such a view was denied or undercut by Christian thinkers, who tended to separate self-interest and altruism sharply and to argue for the importance of the latter to the detriment of the former. At the same time, however, Christian thinkers such as Augustine (354–430) appropriated the ethics of Plato together with Stoicism to form the characteristic Christian view of ethics that Friedrich Nietzsche later reviled in the nineteenth century. In the thirteenth century, Thomas Aquinas appropriated the ethical views of Aristotle and wed them with the natural law tradition of the Stoics to argue that being ethical was built into human nature, where being ethical meant obeying the laws of God.

NATURAL LAW VERSUS SOCIAL CONTRACT

Historically, therefore, the key issue of ethics has concerned the self-interest of the individual (egoism) in relation to the welfare of others (altruism), with ethics pertaining primarily to actions that involve the welfare of others. A key distinction was that between natural law
theory and social contract theory, which maintained that morality was conventional, not natural, and tied to the social conventions of one’s larger society. Hence, being moral was not part of human nature, but rather imposed upon human nature by society.

Both of these issues—egoism versus altruism, and natural law theory versus social contract theory—emerge in clear relief in modern times in the views of Hugo Grotius (1583–1645), Samuel von Pufendorf (1632–1694), and especially Thomas Hobbes (1588–1679), the most important ethical theorist of the seventeenth century. In his immensely influential work *Leviathan* (1651), Hobbes clearly set forth an influential version of the social contract theory, in which he maintained that people originally existed in a state of nature without social laws or morals. This is a state of “all against law,” unbridled egoism, in which life was “solitary, poor, nasty, brutish and short” (p. 92). People come together, Hobbes said, and agree to a social contract whereby they give up some of their liberties and rights in exchange for the security lodged in a larger system of law and order, which protects their interests. According to Hobbes, one behaves morally because of the benefits one receives from doing so; in short, because it is rational to do so. However, if one could benefit oneself by disobeying a moral convention without getting caught, it would be rationally defensible to do so. In a sense, therefore, morality is based upon rationality, and the kind of rationality present here is the economic rationality present in rational choice theory—pursuing those behavioral means that are most likely to result in the ends one desires.

Similar social contract theories can be found, in substantially different forms, in the works of John Locke, Jean-Jacques Rousseau, David Hume, and even Immanuel Kant. These are the main representatives of the social contract tradition.

The natural law theory also has its famous modern agents. Locke, who was also a representative of the social contract tradition, argued that human beings had certain “natural rights” given to them by their creator, who had hardwired these rights, as it were, into human nature. There is, Locke argued, a natural psychological law governing how human beings act, based upon their desires. It is natural for humans to strive to satisfy these desires, and it is the duty of others to allow them to pursue these interests. Locke is thus a classical liberal (like John Stuart Mill) and the inspiration for later libertarianism.

**UTILITARIANISM**

Hobbes said individuals behave morally out of fear of the government, but one could also argue that there are elements of human nature that support this. This was the view of David Hume and Adam Smith, who argued against both the natural law tradition and the social contract tradition. According to Hume and Smith, humans are born with certain moral sentiments or feelings of sympathy for their fellow creatures. These feelings, a basic part of human nature, motivated individuals to care about others and to take into consideration their interests and needs. Hence, it was not rationality so much as it was emotional makeup that turned us into moral creatures.

For subsequent, post-Enlightenment thinkers, the conflict between natural law and social contract theory gave way to what is one of the major moral philosophies of modern times: utilitarianism. Although the writings of earlier individuals such as Hume contained utilitarian themes, it was Jeremy Bentham and John Stuart Mill who set forth the theory of utilitarianism: One should always act so as to produce the greatest benefit for the greatest number of individuals. This is a version of consequentialism, the view that it is the consequences of an action (or a rule governing that action) that determine its moral acceptability. As such, it has been interpreted as a commitment not to egoism, nor to altruism, but to universalism—treat everyone (including oneself) as an individual and determine the total amount of happiness to be produced by an action. Twentieth-century thinkers proposed several important modifications in this formulation, notably “rule utilitarianism,” which maintains that an action is right or wrong in virtue of the good or bad consequences of the rule under which it falls.

**DEONTOLOGY**

In Enlightenment and post-Enlightenment thought, the philosophical debate about ethics has, until fairly recently, turned on the question of the adequacy of utilitarianism in relation to its historical rival—deontology (sometimes called “formalism”). Deontology is the view that there are fundamental human duties that are independent of their good or bad consequences; some actions are morally right or morally wrong by virtue of certain inherent properties in the actions themselves, for example, by virtue of their possessing or not possessing certain rational properties such as universalizability, reversibility, and so on. Immanuel Kant is the most famous deontologist (although in the twentieth century other individuals such as W. D. Ross championed a somewhat similar cause). Kantian ethics is concerned with advocating absolute duties (prohibitions) against lying, killing, and so on. The basis of such absolute duties derives, Kant thought, from the moral agent’s rational nature pure and simple, by virtue of one’s unique nature as a universal lawgiver (prescriber). There are several formulations of Kant’s famous “categorical imperative”: “Act as though the maxim of your action becomes by your will a universal law of nature” (2002, p. 222). and “Act in such a way that you
treat humanity, whether in your own person or in any other person, always at the same time as an end, never merely as a means” (2002, pp. 229–230). Both formulations of the categorical imperative were rooted in our rational nature as autonomous agents.

**VIRTUE THEORY AND RATIONAL CHOICE THEORY**

The classic moral debate typically has been presented to be between utilitarianism and deontology, although recently virtue theory has become a third contender. According to virtue theory, exemplified especially by Aristotle, a morally proper action is one that flows from an internal moral virtue or good character trait of the moral agent. From the point of view of social science (especially psychology and economics), the status of moral principles has always been somewhat problematic. Assuming that such social sciences are empirical (“positive”) sciences and hence concerned with ascertaining the factual nature of the social world, how can normative principles fit into such an empirical science?

According to the now-classic distinction championed by Hume and Kant and pressed even further by G. E. Moore (1873–1958), the fact-value (is-ought) distinction is a categorical one in which one can never proceed to draw an inference from a factual statement to a statement about values, or “oughts.” Hence, if the social sciences are concerned exclusively with factual matters, the status of ethics in the social sciences has always remained problematic. If one is to have a unified, consistent empirical social science, committed to naturalism (in which only the natural world exists, and one can obtain knowledge only by employing the methods of the natural sciences), one might study ethical behavior empirically, describing how people actually behave or think about morality, or one might avoid ethical principles altogether (because they fall outside the realm of positive science). The latter course is problematic because the social sciences are knee-deep in value judgments and normative principles (e.g., don’t fake your data, don’t harm your research subjects, etc.). Furthermore, at least in the case of economics, assumptions about rationality are unavoidable: Economic behavior seems to presuppose that the economic agent is a rational one pursuing one’s preferences (desires, utilities) in a rational (instrumental) way. The only possibility, therefore, would seem to be a naturalistic ethics: Produce and rationally defend a set of normative principles, but do so in a completely naturalistic way. One candidate for such a naturalistic ethics is modern contractarianism.

Rational choice theory is a descendant of utilitarianism, with a change from interpersonal preference functions to Pareto preference functions (this occurred in the early twentieth century). Contractarianism is a descendant of the social contract theory of Hobbes and has two versions: Hobbesian contractarianism and Kantian contractarianism. John Rawls (1921–2002) is the best-known Kantian contractarian (or “contractualist”), who attempts to establish a set of normative principles involving justice on the basis of what individuals would agree to in an original state of nature (the original position). However, this position begins with normativity already built in (because individuals are under “a veil of ignorance”). For many individuals, such a view is not sufficiently naturalistic. The other view is Hobbesian contractarianism, in which the goal is to derive normative principles involving justice from an original position in which nothing normative is presupposed, except the notion that the agents are rational agents attempting to maximize their utilities (preferences, desires). The main philosophical representative of this theory is David Gauthier (b. 1932), although there are social scientists who also advocate a similar position.

Beginning with the “prisoner’s dilemma,” Gauthier (and others inspired by this approach) attempt to show that certain kinds of prisoners’ dilemmas (e.g., iterated versions) will necessarily result in cooperation, promise keeping, and justice. In short, according to this model, it is possible to show that it is rational to engage in moral behavior—understanding “rationality” in something like the standard economic sense (i.e., instrumental rationality). If such a proposal were plausible, and many doubt that it is, one would have a naturalistic ethics for the social sciences. An alternative account, one going back to Hume and Smith, would be to argue that altruism is innate in humans, that we are born with feelings of sympathy, and that such feelings are a sufficient ground to justify moral principles. There are, of course, other versions of naturalistic ethics, and many moral philosophers are skeptical of such attempts to construct a naturalistic ethics. This applies, for example, to contemporary Kantians who reject all attempts to naturalize ethics. If they are correct, then insofar as the social sciences depend upon moral principles, the social sciences would be unable to rationally ground such principles using standard social science methods and methodology. This would, once again, raise the question of the adequacy and hegemony of the social sciences—at least a certain conception of them—and thus, indirectly, of our scientific worldview. Needless to say, such an issue remains a crucial one to address in reflections upon the status of the social sciences in the twenty-first century.

**Philosophy, Political**

The scholarly analysis of politics, as the realm where human beings interact and associate with each other, tends to be approached through two partly overlapping but distinct disciplines: political science and political philosophy. While political science seeks to impose order or meaning upon phenomena in the real world through observation, experimentation, and measurement, political philosophy covers more abstract and more fundamental thoughts about politics. Hence, while political science may be interested in analyzing the workings of the democratic process in a particular society (e.g., the factors that determine voter behavior in democratic elections), political philosophy takes a step back and asks second-order questions about the political concepts we use in those analyses: What is actually meant by democracy? What rights and duties should be bestowed on the individuals living in a democracy? And do we need political institutions such as a state, a government, or the law to ensure that these rights are upheld and the duties honored?

Although infinitely more could be added, these are the questions that have proved enduringly important to human life in general and the discipline of philosophy in particular, today as much as two hundred or two thousand years ago. The student of the discipline is therefore exposed to concepts, ideas, and philosophers that often date back to Greek antiquity.

**AUTHORITY, THE STATE, AND THE SOCIAL CONTRACT**

Arguably, the most fundamental concern of political philosophy is the question of political authority. In its broadest sense, authority is the means by which one person can make others do what they would otherwise not have done. It is usefully distinguished from the related concept of power, in that both may be forms of control, but the latter refers to the ability to influence the behavior of others.
(through persuasion or coercion), whereas the former defines the right to do so (expressed through the moral duty on the part of the ruled to obey). While thus "might does not make right," the question remains when we should regard authority over us as rightfully exercised by the ruler and therefore morally justified and, crucially, what the source of that authority should be. In the view of some, notably anarchists, authority is always impermissible, and the only form of human association is one in which there are no persons or institutions issuing commands. Others believe in divine authority, whereby God's supreme might or goodness is granted, initially by God to Adam in the Garden of Eden and subsequently to God's descendants on earth who then claim unquestionable rule, for example as king over Egypt or as pope over Christendom.

The most common justification of authority, however, is the idea of the social contract as developed in various versions by philosophers such as Thomas Hobbes (1588–1679), John Locke (1632–1704), Jean-Jacques Rousseau (1712–1778), Immanuel Kant (1724–1804), and even Plato (427–347 BCE). The writings of the first three in particular had considerable impact on the creation of democratic states in the seventeenth and eighteenth centuries. Significant differences between them notwithstanding, these thinkers ask us to imagine a hypothetical "state of nature" before there is any political authority. Individuals are on their own, in the sense that there is no higher authority that would command their obedience or protect their interests and possessions. Since their self-interested behavior may lead to a situation of conflict between them, individuals agree to establish institutions that define and impartially enforce binding decisions on them so that their lives are preserved in a physically and economically more secure environment. They enter a voluntary agreement, the social contract, to create a state to which they hand over their power and whose laws and actions they pledge to abide by. In return, the state guarantees the protection of individuals' liberties at home and against aggression from abroad. Most democracies possess features that guarantee the legitimacy of this form of authority, such as constitutional governments, regular elections, a competitive party system, and checks and balances between the executive, legislature, and judiciary.

UTILITARIANISM, JUSTICE, AND THE INTERNATIONAL REALM

Once individuals have agreed to live in a state so depicted, the question arises as to what sorts of institutions they ought to try to bring about politically. In the nineteenth century, the British philosopher Jeremy Bentham (1748–1832) and his student John Stuart Mill (1806–1873) established a broad consensus, commonly referred to as utilitarianism, according to which the yardstick in assessing political institutions is the happiness, or pleasure, of the people affected by them. On this view, all human beings are motivated by self-interest, which can be defined as the desire to avoid pain and maximize pleasure. Institutions should therefore act so as to promote the greatest happiness of the greatest number of people, which is made possible by measuring happiness in terms of its intensity and duration (and calling the resulting metric utility).

By virtue of its mathematical and therefore ostensibly objective approach to making moral judgments, utilitarianism succeeded in having a lasting impact upon political issues in real life, most notably the social, political, and legal reforms in nineteenth-century Britain. Yet, it also became heavily criticized for its individualistic view of human nature, which is both asocial and ahistorical, as well as its disregard for the divergent concerns, agendas, needs, powers, and wealth of individuals. What is more, the focus on utility maximization makes utilitarianism endorse acts widely considered to be unjust. To use a simplified example, it is morally wrong and a violation of human rights to harvest someone's organs, and kill one life in the process, even though in numeric terms utility is maximized because three patients could be saved by the donor's liver, heart, and lung respectively.

It took more than a century before a similarly comprehensive theoretical framework emerged as an alternative ordering principle of society. In 1971 the American philosopher John Rawls (1921–2002) published A Theory of Justice, in which he developed a contract-based argument of how to arrive at the principles by which members of a just society would want to distribute rights, duties, and goods amongst each other. To prevent asymmetries of power and wealth bringing about unjust contracts and principles, he asks us to imagine an "original position" where individuals exist behind a "veil of ignorance" and are deprived of any knowledge about their own particular properties, including their social status, wealth, talents, gender, and race. Free and rational agents, so he argues, would then agree to commit to two basic principles: a liberal principle according to which each person is to have an equal right to the most extensive liberty compatible with a similar liberty for others, and an egalitarian “difference principle,” whereby social and economic inequalities are only justified if they are to the greatest benefit of the least advantaged. With this device, Rawls seeks to ensure that individuals are not penalized for factors over which they have no control, such as gender, race, and genetic inheritance, while still maintaining a level of inequality that provides them with sufficient incentive for economic enterprise.

The technological, social, and political developments the world saw in the second half of the twentieth century
induced political philosophy to extend its thematic and geographical scope and engage with issues beyond the immediate set-up of the individual society. Not only were attempts made to transfer Rawls's conception of justice from the domestic to the international realm, but other cross-border issues began to be explored as well, such as the protection of ethnic minorities; the right of nations to wage (just) wars; secession and national self-determination; the universal applicability of human rights; as well as environmentalism and sociobiology. These topics have since come to define the research frontier of the discipline, and should continue to do so for the foreseeable future.

POSTMODERNISM AS A CHALLENGE TO THE DISCIPLINE

Political philosophy of the type described above is driven by a rigid analytical methodology, and hence it is often referred to as analytical philosophy. Yet, as a scholarly discourse it dominates the academic community much more in the Anglo-American sphere than in other regions. In continental Europe, for example, a school of thought called postmodernism holds that because society in the twentieth century is increasingly based on shared information and communication, all knowledge must be dependent on discourse and language and can by definition only be partial and local. What is more, language itself is a product of complex relations of power (on the part of the media, politicians, businesses, and other interest groups). Postmodernists such as Martin Heidegger (1889–1976), Michel Foucault (1926–1984), and Jacques Derrida (1930–2004) therefore deny that philosophy is capable of standing above such power relations. It cannot represent a moral or rational high point from which claims about knowledge, universally applicable values, and objective truths can be made. Rather, philosophy is an intrinsic part of the power relations it purports to analyze.

The postmodern disruption serves as a useful reminder to us that philosophy consists of many legitimate ethical and political positions and that the concepts employed by the discipline may not always be as neutral as they appear to be.

PHILOSOPHY OF SCIENCE

Everyone takes for granted scientific progress in the natural sciences, but the topic raises controversy about the social sciences. Philosophy of science attempts to answer questions like: What makes some practice scientific? Why is science so successful? Why is there unevenness in the success of science? But it also attempts to explain what these questions might mean. Because social scientists so often deal with difficult and controversial topics—the role of religion in human welfare, tolerance for cultural difference, psychological bias and stereotyping—they routinely turn to philosophy of science for guidance.

PHILOSOPHY OF SCIENCE IN THE SOCIAL SCIENCES

Three systematic theories in the philosophy of science emerged at different times in the twentieth century—logical empiricism, scientific realism, and social constructivism. Each position is designed to explain apparent scientific development or progress. Logical empiricism—in many ways the dominant outlook among methodologically reflective psychologists and social scientists in the twentieth century—states that scientific knowledge is restricted to observable phenomena, and that theories are mere instruments for generating hypotheses to be tested by observation (for the modern version, see van Fraassen 1980). Scientific Realism, as elaborated by J. J. C. Smart (1968), Hilary Putnam (1975), and Richard Boyd (1984), is the alternative view that the best scientific theories should be understood as approximately accurate descriptions of a mind-independent reality, in both its observable (empirical) and unobservable (theoretical) aspects. Social constructivism (Kuhn 1962) is the doctrine that scientific knowledge depends so deeply on theory that it is best understood as the result of a construction rather than a discovery procedure. There are also complicated hybrids of these three views, such as Arthur Fine's natural ontological attitude (Fine [1986] 1996).
Many social scientists accept another philosophical doctrine: philosophical naturalism. Naturalism is the doctrine that philosophy is methodologically and perhaps (meta)physically continuous with the natural sciences. According to this view, a philosophical doctrine about the social sciences gets tested and confirmed or disconfirmed in the same way hypotheses in the natural sciences do—by prediction and measurement.

Traditional methods in the social sciences did not emphasize prediction and measurement; the social sciences were typified by narrative methods (Martin and McIntyre 1994). Narrative methods typically describe the course of behavior by appealing to actors’ intentions and construct a story of how an effect came about. Narration has been a central method in social sciences such as anthropology and history, where a chief goal is to describe the course of behavior in a particular cultural setting or epoch. The anthropological writings of Bronislaw Malinowski, such as Coral Gardens and their Magic (1935) or Argonauts of the Western Pacific (1922), and E. E. Evans-Pritchard’s Witchcraft, Oracles, and Magic Among the Azande (1937) are prime examples of the narrative method, as are Garrett Mattingly’s Armada (1959) and classics by Oswald Spengler (The Decline of the West [1928]) and Edward Gibbon (The Decline and Fall of the Roman Empire [1776–1788]) in history. Most of the social sciences have developed clever methods to expand the methodological power of their fields (Joseph Henrich, Richard Thaler, Steven Leavitt), but much contemporary work in anthropology, history, and the clinical arm of psychology remains in the narrative tradition. Because such appeals would be wholly inappropriate for explanations in physics, chemistry, and biology, narrative methods are unique to the social sciences.

Measurement has always played an important role in the natural sciences, from Isaac Newton’s (1642–1727) laws of motion to Robert Boyle’s (1627–1691) law based on the measurement of heat, pressure, and the volume of an enclosed container. The social sciences make room for another method of inquiry that uses the tools of statistical measurement. Sociology uses such techniques as causal modeling. Economics also uses causal models, as well as a wide range of regression techniques. Psychology uses experimental design and the standard array of statistical tests: analysis of variance, t-tests, multivariate analysis, and so on.

So there are some differences between the methods of inquiry in the natural and social sciences, but there is also broad agreement about such topics as the importance of measurement (Trout 1998). Other shared norms place a premium on observability and testability, however unevenly applied. Testability—at least in the experimental sense—is not a practical requirement in evolutionary theory, for example. But the testability criterion does represent an ideal. Scientific assertions, and the theories that recommend them, are testable: There is a well-established generalization in psychology that words that are more frequent in a language are identified more quickly, and in economics that markets clear, to cite just two examples.

Early philosophy of science made testability, verifiability, and falsifiability a necessary condition for scientific status—and this was a mistake. The philosophy of science has a regrettable record when it dictates the standards of science; it performs much better when it extracts lessons from reliable scientific practice. So, while it makes sense to ask what the ideal norms are in the philosophy of science, the intellectual trend runs in the opposite direction: What features of the practice of science are so successful that they deserve to be elevated to a normative standard in the philosophy of science?

METHODOLOGICAL DISPUTES IN SOCIAL INQUIRY

The logical positivists, following their interpretation of David Hume’s (1711–1776) dictum that all nontautological knowledge arises from experience, attempted to formulate a way of distinguishing claims that have empirical content—and thus could be adjudicated objectively by appeal to observable evidence—from those that do not have empirical content. Fortified by the meaning-atomism of the early Rudolph Carnap (1891–1970) and Ludwig Wittgenstein (1889–1951), the logical positivists hoped to catch and identify those claims that are metaphysical, that describe conditions that are beyond experience and thus empirically meaningless. The principle of verifiability was formulated in a variety of ways (for the scientific rationale that was in the air at the time, see Schlick [1932–1933] 1991). But ultimately, the principle of verifiability could not accommodate the actual, epistemically reliable practices of scientists; indeed, it contradicted those practices. Scientists made patent metaphysical assertions, and no amount of “rational reconstruction” could cleanse that vocabulary. Indeed, it is now an adage that, when reliable scientific practice meets exacting philosophical principle, philosophical principle either yields or faces embarrassment. (For an excellent introductory overview of twentieth-century philosophy of science, see Godfrey-Smith 2003.)

With similar concerns about identifying and diagnosing intellectually disreputable practices, Karl Popper (1902–1994) proposed the principle of falsifiability—that the hallmark of a scientific theory is that it is falsifiable under empirical testing. Put more formally: a theory is potentially scientific if and only if there are possible observations that would falsify or refute it. According to
Popper’s vision, that is what scientists do—they make conjectures and attempt to refute them.

Although Popper’s proposal proved enormously influential, it turned out that neither verifiability nor falsifiability captured the practices of science. Scientists attempt to confirm and not refute their hypotheses. Moreover, their expressions are not meaningless without an experimental test to verify their hypotheses. In addition, Popper’s notion of corroboration—the tendency of a hypothesis to survive repeated attempts at refutation—was too weak to capture the scientific practice of confirmation.

Thomas Kuhn (1922–1996) was a classic social constructivist. He argued that science is not progressive or even continuous, but is typified by a series of “ruptures” in the normal process of science. These ruptures, produced by scientific revolutions, make theories and the items they refer to “incommensurable,” to use Kuhn’s term. Scientists separated by fundamentally different theories “see different worlds.”

Imre Lakatos’s (1922–1974) philosophy of science deemed Kuhn’s view too much of a concession to holism and relativism. Departing from Carnap’s and Popper’s focus on testing individual hypotheses, however, Lakatos took the entire theory as the unit of analysis. When confronted with falsifying evidence, scientists will protect the core of their favored theory from refutation by introducing auxiliary hypotheses. In response to Kuhn, Lakatos argued that a progressive (rather than stagnating) research program reflects growth, as well as findings that are novel and surprising.

LESSONS FROM PHILOSOPHY OF SCIENCE TO SOCIAL SCIENTISTS

Social scientists have long desired to extract information from catalogs of demographic data. But the reigning philosophical and social science standards in hypothesis testing had prohibited the search for correlations after the fact; all hypothesis tests have to be a priori. With new, powerful data-storing capacities, social scientists have developed sophisticated post hoc search and “data-mining” methods (Spirtes et al. 2001). These methods have allowed the social sciences to extract causal information from correlation data about important social issues, such as the efficacy of the Head Start program for low-income children.

Philosophy of science has built its theories—such as realism, empiricism, and constructivism—not just on methodological success but also on historical evidence of scientific progress. This evidence consists of case studies, often casually assembled and intuitively interpreted. But philosophers of science have been alert to the findings in the psychology of problem solving establishing the inaccuracy of intuitive judgments. Accordingly, philosophy of science has adopted a more quantitative focus, one that replaces narratives with models, and stories about episodes with data.

Earlier antimetaphysical philosophy of science was profoundly suspicious of causal notions. But with the demise of antimetaphysical philosophy of science, the causal properties of scientific items have received close attention. Moreover, individual causal properties—like being wealthy, a Democrat, or a member of a union—can be involved in different disciplines. These causal properties produce not only unified explanations of phenomena, but also a more unified image of the world. In a round-about way, then, contemporary philosophy of science, by focusing on causal properties generally rather than observable properties specifically, completed the unity of science program begun by the logical positivists.

The logical positivist model was one of unification by reduction, of higher-level to lower-level sciences. According to this view, sociology and economics are reducible to psychology, psychology is reducible to biology, biology to chemistry, and chemistry to physics. But the course actually taken by the social sciences has not confirmed this logical positivist account. Instead, adjacent portions of the disciplines appear to get integrated rather than assimilated, reduced, or eliminated. If anything, the social sciences have undergone a proliferation of durable specialization, a model of unification confirmed by the increasing interdisciplinary activity in these disciplines.

PHOBIA

Phobias are morbid, irrational fear reactions to specific objects and situations. Phobias are among the most prevalent mental disorders worldwide. The term phobia comes from the name Phobos, the son of Aries, the Greek war god. Phobos was so fearsome-looking that enemies on the battlefield became panic-stricken when they saw him. Specific phobias are named by combining the Greek word for the object or situation with phobia. Thus, fear of thunder becomes brontophobia, and fear of closed spaces becomes claustrophobia. Phobias have been described for at least 2,500 years, going back to the ancient Greek physician Hippocrates (c. 460–377 BCE), the “father of medicine.”

Phobias are classified as types of anxiety disorders by the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR, 2000). The major diagnostic characteristics of a phobia are that an individual consistently reacts to some object or situation with intense fear and seeks to escape or avoid that stimulus; this fear is sufficiently strong that it interferes with the person’s normal functioning. Three types of phobias are differentiated by the nature of the circumstances that precipitate the strong fear reaction: specific phobia, social phobia, and agoraphobia.

Specific phobias include fears of clearly identifiable objects or situations, such as looking down from a tall building or seeing a snake. There are four basic subtypes of specific phobia: natural environment (water, storms); animals (snakes, spiders); situations (enclosed places, bridges); and blood, injections, and injuries (dentistry). Specific phobias that do not fall into these four subtypes are classified as other.

Social phobia, also called social anxiety disorder, is defined by a persistent and intense fear reaction and avoidance of social and performance situations in which one might be embarrassed or negatively evaluated by others. Common social phobic situations include public speaking, meeting strangers or persons of the opposite sex, using public restrooms, and writing one's name in public. Social phobias typically begin in adolescence or young adulthood.

Agoraphobia, literally “fear of open spaces,” is more accurately the fear of having a panic attack in a public place, such as a shopping mall or a theater, from which one might have difficulty escaping to safety. Due to this fear, agoraphobics avoid public situations and, in many cases, become totally housebound.

Phobias share many characteristics with other anxiety disorders. For example, a person with panic disorder experiences intense panic attacks that are similar to what phobics experience, except that these attacks seem to come out of nowhere and are not clearly attached to specific cir-
Phobia

The majority of agoraphobics will be diagnosed as having panic disorder with agoraphobia. Post-traumatic stress disorder is also similar to phobias in that following a severely traumatic experience in which people believe that they or someone else might die (such as war or rape), some people continue to react with intense fear and avoidance when reminded of the original trauma.

Although the exact details of how phobias develop are not clear, there is a broad consensus that classical or Pavlovian conditioning-like processes are involved, in which an individual experiences a strong fear reaction in the presence of a specific object or situation, forming an associative link. Subsequently, when the object is reexperienced, it triggers a panic attack. Recent theories suggest that cognitive or thinking processes contribute to some phobia development. For example, the mere observation of another person being injured or frightened can initiate a phobia. Although most phobias develop via conditioning or observation, a considerable number of phobics have no recollection of having been frightened or injured in the presence of their phobic stimulus, either directly or vicariously.

Evolutionary theory enters in as well to explain why some objects are more frequently found to be phobic stimuli than others. American psychologist Martin Seligman’s theory of biological preparedness hypothesizes that due to their evolutionary significance as potential dangers, we are prone (prepared) to develop conditioned responses more readily to objects that were dangers in our evolutionary past, such as small, poisonous animals (e.g., snakes). We are less prone to develop conditioned responses to more modern but equally dangerous stimuli, such as guns.

Specific phobias are the most successfully treated of the anxiety disorders. The basic paradigm guiding most successful treatment follows from the conceptualization of the phobia’s origin as a conditioning-like process: To overcome or to extinguish a conditioned fear reaction, the phobic must engage the stimulus that elicits the panic reaction. With repeated exposure to the triggering stimulus, the panic reaction diminishes progressively until it is extinguished. The engagement with the triggering stimulus can be done gradually in small increments, or the phobic can be immersed or confronted with the stimulus full-strength. When presented in small increments, an anxiety hierarchy can be constructed that consists of a series of graded representations of the feared stimulus. Starting at the bottom, each item is presented to the phobic, who tolerates the fear until it diminishes, after which the phobic moves up to the next item in the hierarchy. Alternately, a phobic might be immersed in the feared stimulus through a procedure called flooding. Here the stimulus is presented at full strength, eliciting a strong fear reaction that diminishes over time.

These exposures can be accomplished with direct, live confrontation with the feared stimulus or through a procedure in which the patient brings elements of the anxiety hierarchy to mind as mental images. In a version of this treatment, called systematic desensitization, patients learn deep relaxation, which helps them remain relaxed as each item of the hierarchy is imagined. With repetition, each item is progressively mastered. Although systematic desensitization was the first method found to be truly efficacious in treating phobias, it requires an average of eleven one-hour treatment sessions. Live, direct exposure to the stimulus elements extinguishes the fear reaction more quickly. Swedish psychologist Lars-Goran Öst has shown that a single five-hour session of live exposure is highly effective for treating many phobias. More recently, computer-generated stimuli presented as virtual reality have been shown to be effective for treating phobias.

In practice, several of these approaches are often combined with cognitive mechanisms that help phobics believe that they can tolerate the feared stimulus. One method, called modeling, is particularly effective with children. Dog-fearful children, for example, observe nonfearful children playing safely with dogs, and this exposure by observation diminishes the phobic child’s fear.

Similar methods using live or imagined exposure to a feared situation are also effective for social phobia and agoraphobia. However, in contrast to specific phobias, where psychotropic drugs are generally ineffective, some medications can assist in the treatment of social and agoraphobia. A class of antianxiety drugs called benzodiazepines can be useful adjuncts to exposure treatments, but such drugs must be used with caution because they are addictive. Another class of medication, selective serotonin reuptake inhibitors, can also assist in some cases by diminishing the number of panic attacks among social phobics and agoraphobics. Although effective, the exact psychological mechanisms underlying these phobia treatments remain unclear.

PHYSICAL CAPITAL
Capital is a contested concept and thus its components are contested. Physical capital generally refers to plant and equipment, while financial capital refers to money. The first is a matter of physics and biology. The latter is an understanding among people allocating opportunities—an institution. Financial capital is part of the social system controlling the physics of production and the distribution of income. Physical capital is a produced good used in further production—not used up when a consumer good is made. But, the relevant time period needs definition. Stocks of raw materials and inventory of finished goods are usually referred to as circulating capital. Capital has a beneficent connotation in modern societies and thus many adjectives are added to capital, such as social capital, cultural capital, and human capital.

Some aggregative measure of physical capital is necessary if one is to relate its quantity to cross-country or time series differences in physical output (economic growth). But there is no way to measure a collection of physical things that differ in quality. How is one to add up a computer and a blast furnace and the change in their capacity over time? This presents an index number problem. At first glance, it appears that capital might be aggregated in terms of money invested. But a unit of money invested in the past may buy a quite different machine today. There are no convenient or unambiguous units of technology. Counting the number of scientists or patents or putting an increasing weight on investment over time only hints at changing technology. If physical capital is measured by its value today, the aggregate is influenced by the rate of profit and interest, making the measure circular. The quantity of capital would be sensitive to the business cycle and capacity utilization. In short, the money value of plant and equipment cannot be used as a proxy for the amount of physical things used in production. If capital cannot be measured unambiguously, it is impossible to determine its marginal value product and use it to justify factor shares.

Alternative capital theories and definitions are part of the history of legitimating distribution. The payment of interest was justified to motivate waiting by owners of financial assets. If the rate of interest reflected the marginal value product of capital, it could justify the income of capitalists. But the argument becomes circular if the value of capital stock is influenced by income distribution. The value of capital cannot be ascertained independently of the rate of interest.

Harrod-Domar models of growth held the ratio of financial capital to labor constant, in spite of empirical contradiction. It would be useful if investments could be ranked according to the marginal product of capital. The so-called Cambridge capital theory controversy arose over another long-held notion that a falling rate of profit would lead to more capital intensive techniques. However, it was noted that a technique profitable at one rate of interest might not be at another and may then become profitable again at still higher rates. This reswitching phenomena upset the conception of a unique equilibrium. The conceptual problem turns on the fact that capital is not homogeneous. It is questionable to claim that the rate of profit equals the marginal value product of financial capital.

Harrod-Domar models led to policy recommendations emphasizing saving as the means to economic growth. Poor countries were encouraged to save more. When it was clear that it was hard for the poor to save, development aid took the form of loans and capital grants. Growth then depended on exogenous inputs. The results were uneven and many countries had little growth, but huge debts. Modern growth theory has shifted attention to endogenous factors such as research and development—changing the quality of physical capital and preventing diminishing returns. New growth theory suggests that less-than-perfect competition and the promise of extraordinary profits may be necessary to entice innovation. The empirical record is mixed. The “Asian Tigers” had high savings rates, but little research and development of their own. The United States has high growth, but saves little. In rich countries such as the United States, the asserted relationship between the rate of profit and physical capital formation is used to justify tax breaks for the wealthy, even though the higher profit may be used to acquire other financial assets rather than build new plant and equipment.

Increasing the volume of financial capital transferred to poor countries may not increase growth if it is used for consumption (or fraudulently stolen by the elite) rather than investment. And, even if it is invested, it may not be invested in the most advantageous physical projects and sectors, or it may be poorly managed. Modern technology may be in place, but inputs may not be available in a
timely fashion. The picture is complicated by the fact that some sources of growth, such as computers, are not capital intensive, while such things as petrochemicals and power-generation plants are. Both physical labor and physical capital have problems of aggregation because of different qualities. An hour of work from illiterate laborers is not the same as an hour from skilled workers. This led to the conceptualization of human capital. But, again, readily available measures of years of education beg many qualitative problems, as was the case for technology over time. Even land (natural resources) is difficult to aggregate because of differences in quality and kind. The ecological system can degrade without a production or financial impact in the short run.

The coordination of physical inputs to production and its distribution is a matter of institutions affecting learning and incentives. In short, the distribution of income is not some natural result of supply and demand, but of the distribution of power. It would be convenient for growth accounting and legitimation of income distribution if it were easy to clearly relate increments of physical and financial capital to increments of growth, but alas this problem has not been solved. Confusion arises when financial and physical capital inputs are mixed together in empirical studies.

PHYSICAL QUALITY OF LIFE INDEX

Rapid economic growth raised average living standards in many countries around the globe in the 1960s and the early 1970s, but inequality also emerged as an issue. Prosperity bypassed large segments of the population, especially in developing countries, which stimulated a search for meaningful measures of poverty that were readily calculable. Some people saw progress in the segments of the population that lacked essential human needs, such as clean water, basic medical care, suitable housing, and adequate calories. Although interesting and useful, this approach also required considerable survey evidence, which was expensive and often unreliable.

At the behest of the Overseas Development Council, Morris David Morris created the physical quality of life index (PQLI), which assessed conditions in a country from its infant mortality rate, adult literacy rate, and life expectancy at age one (Morris 1979). Nearly all countries routinely reported these data by the 1970s.

The technique first scales each ingredient from 0 to 100, with the end points set to capture the range of historical experience. The infant mortality rate extends from a high of 229 to a low of 7 per thousand (a span of 222); life expectancy at age 1 from a low of 38 to a high of 77 years (a span of 39); and the literacy rate from 0 to 100 (a span of 100). For example, the index value of life expectancy = (100) (life expectancy – 38)/39, which means that an increase in life expectancy of 0.39 years raises the index value by 1 point. Then the indexes of the components are averaged to obtain the overall PQLI.

In principle one could use the PQLI in much the same way as any measure of human welfare, including policy design and assessment, or as a phenomenon to be explained by economic or social models. Econometric work, however, has been limited, in part because imitators and successors have crowded the field. Although the PQLI was designed as a minimal measure of social performance and partly as an antidote to undue emphasis on gross national product (GNP) per capita, its critics have noted that health is counted twice (infant mortality and life expectancy at age one are highly correlated) and that the index omits the material side of the quality of life. Soon other indexes appeared, some with more than 40 components or indicators, including crime, pollution, and suicide rates. Among these, the Human Development Index (HDI) of the United Nations has been the most widely discussed and applied. Created by the economist Mahbub ul Haq in 1990, this index was designed to register the “expansion of choice” provided by good health, knowledge, and access to material goods (United Nations Development Programme 1990). It soon was criticized for lack of attention to inequality and for incorporating a poor measure of knowledge. Thus researchers continue to debate the components of quality of life indexes and the weights that should be given to each. What is suitable, however, depends heavily on how the index will be used.
**Physiocracy**

The term physiocracy means law or rule of nature. It derives from a collection of essays by François Quesnay edited by Pierre Samuel du Pont de Nemours and published in two volumes in 1767–1768 in which the name Physiocratie figures prominently. Quesnay was the uncrowned leader of what was perhaps the first school of thought in economics. The school was highly influential on economic policy matters in France in the period from 1756 to the beginning of the 1770s during the reign of Louis XV. Even more important, it had a decisive impact on the emerging new scientific field of political economy. The school’s relatively small number of followers and their strict adherence to the teachings of Quesnay are presumably responsible for the school also being known as a “sect.” The school’s major members, apart from those already mentioned, were Abbé Nicolas Baudeau, Victor Riqueti, Marquis de Mirabeau, Le Mercier de la Rivière, and François Guillaume Le Trosne. On the natural law underpinnings of physiocratic thought, see Hanz Rieter (1983).

On the physiocrats’ recommendation, in 1763 and 1764 the corn trade, both domestically and abroad, was liberalized in France. The second half of the 1760s saw substantial increases in the corn price, which the public took to have been caused by the liberalization policy. However, there is reason to think that the price increase was the result not so much of grain exports as a series of bad harvests. The experiment was terminated in 1770, and since its failure was blamed on the physiocrats, it comes as no surprise that their influence declined as quickly as it had risen (Weulersse 1910; Hecht 1958). In other countries the ideas of Quesnay and his followers remained important, at least for a while, including especially Germany and Russia.

Quesnay, a surgeon and medical doctor of the king and of Madame de Pompadour, the king’s favorite, came to economics rather late. In 1756 and 1757, in his early sixties, he published entries on Fermiers (tenant farmers) and Grains (corn) for the Encyclopédie edited by Denis Diderot and Jean d’Alembert. Yet his most important contribution to economics was the Tableau économique. Its first version, in 1758, was difficult to understand because of a confusing table with three columns and numerous zigzag lines joining them. Two further editions came out in 1759 (Quesnay 1972). In 1766 came the publication of a substantially revised and improved version of the Tableau in a work titled Analyse de la formule arithmétique du Tableau économique de la distribution des dépenses annuelles d’une Nation agricole. This latter version of the Tableau is the best known (Institut National d’Études Démographiques 1958; Quesnay 1972). It contains the first attempt to describe the intertwined processes of the production, distribution, exchange, and disposal of the riches of a nation in terms of a scheme with two large sectors of the economy—primary production and manufacture—and three social classes—the propertied class (landlords), the “productive class” (farmers), and the “sterile class” (artisans). The economy under consideration is supposed to generate a surplus of commodities over and above what is used up in production in terms of raw materials, tools, and means of subsistence or produit net. However, the surplus concerns only products of the primary sector of the economy, which explains why the people employed there are called “productive.”

The idea at hand may be illustrated in the following way. To produce 1,000 bushels of corn, farmers need 200 bushels for seed, 200 bushels to support themselves and agricultural workers, 100 bushels to feed animals (horses, oxen), and 200 bushels as payment for plows bought from the manufacturing sector. The remaining 300 bushels constitute the net product. Its value in money will be paid as rent to the proprietors of the land (king, nobility, church) for the lease of their lands. The proprietors in turn will buy with money worth 150 bushels precisely that amount of corn from the productive class, and with the remaining money-rent worth another 150 bushels they will buy goods from the sterile class. The sterile class in turn will use the money to buy raw materials and means of subsistence for its artisans worth 150 bushels and transform them into manufactured goods and luxuries sold to the propertied class. The manufacturing sector is “sterile” because, while it uses part of the net product of the agricultural sector and transforms it into some other goods, it does not add to the (value of the) net product (Meek 1962; Pressman 1994).

An important aspect to be stressed is that while only the wealthy proprietors of land get the net product, their revenue is the only source from which the public administration, the army, investments in infrastructure, improvements in the conditions of production in agricul-
Physiocracy

The Tableau has frequently been interpreted as involving an analogy to William Harvey’s (1578-1657) scheme of blood circulation. However, as Rieter (1990) has shown, there is reason to suppose that it involves an analogy with the mechanics of a particular type of clock.

The Tableau contains the first description of an economic system in a state of “simple reproduction,” to use Karl Marx’s concept, or more precisely, of a large kingdom in a state with the highest level of agriculture. Year after year the economy could continue to reproduce itself at the same level, without expansion or contraction, provided there is neither technical progress nor regress and the agricultural and manufacturing products exchange for one another in the market as implied by the Tableau. In fact Quesnay assumed that the “fundamental price” of a product, a concept that anticipates Adam Smith’s concept of “natural price,” covers all physical real costs of production (materials used up, means of subsistence in the support of labourers) and reflects in addition the rule according to which the social surplus product is distributed among different claimants (Vaggi 1987, 1998). The Tableau, however, was only a first step in the physiocrats’ analysis. Concerned with first identifying and then putting to use the potential for growth of the French economy among competing nation states, the physiocrats embarked on an analysis of capital accumulation, the modernization of French agriculture, and more generally the role of technical, organizational, and educational innovations. Hence with the inception of systematic economic thought at the time of the transition from feudalism to capitalism in France, the problem of the dynamism of the economic system immediately made an appearance. The physiocrats opted especially in favor of productivity-enhancing measures in agriculture and against sterile luxury consumption. Therefore the Tableau contained not only an ex-post analysis (national income accounting, input-output) and ex-ante analysis (circular flow and a much disputed discussion of development and growth) but also a manual for economic and social policy; see especially Quesnay’s thirty “maximes générales du gouvernement d’un Royaume agricole” (Du Pont de Nemours, vol. 1, pp. 99ff.).

The physiocrats were criticized by, among others, Achille-Nicolas Isnard (1781), who argued that the impression they generated that only agriculture was productive was closely related to the system of prices underlying their schema. These prices were such that the entire net product was indeed appropriated by the landowners. Other rules of distribution would immediately reveal the peculiarity of the physiocratic doctrine and the untenability of its proponents’ concept of productivity. Smith was full of praise for Quesnay and his disciples and for a while tinkered with the idea of dedicating The Wealth of Nations (1776) to Quesnay. However, he too found the particular form of the physiocratic concept of productivity difficult to sustain and explicitly reckoned manufactures to those industries in which “productive” labor is performed. “Unproductive” labor is now essentially identified with services that generate products that cannot be accumulated. Marx considered the physiocrats “the true fathers of modern political economy” (Marx 1963, p. 44) and dubbed the Tableau “an extremely brilliant conception” (Marx 1956, p. 344). He developed his own schemes of simple and extended reproduction taking it as a starting point (Gehrke and Kurz 1995). Wassily Leontief (1941) saw his own input-output analysis as following in the direct lineage of the Tableau. For an attempt to locate the Tableau in the prehistory of input-output analysis, see Heinz D. Kurz and Neri Salvadori (2000). Piero Sraffa (1960) saw his return to the classical viewpoint in the theory of value and distribution as rooted in the Tableau.

PIAGET, JEAN
1896–1980
Considered by many to be the founder of modern developmental psychology, the Swiss psychologist Jean Piaget devoted his researches to children's distinctive ways of knowing and to the process of developmental change leading toward adult thought. He charted a sequence of stages in children's intellectual development whose manifestations encompass domains ranging from logical reasoning to emotional development. Trained in biology and philosophy, Piaget extrapolated from his studies of mollusks in their natural habitat to a conception of the development of intelligence in children as a progressive adaptation, tending toward ever greater equilibrium, with its reciprocal aspects of the "assimilation" of new information to existing concepts and the "accommodation" (i.e., modification) of the concepts to the new information. He viewed the development of intelligence, in turn, as the foundation of a "genetic epistemology," a theory of knowledge that conceived the development of ideas as part of their essence. On the basis of his observations of children's cognitive development and his claim that children's own action catalyzes that development, Piaget altered the face of psychology and education.

BASIC CONCEPTS:
DEVELOPMENTAL STAGES
Piaget became convinced that children exhibit a distinctive type of thinking, as opposed to simply flawed adult thought, when, as a young associate working on intelligence testing in the laboratory of Alfred Binet (1857–1911), he noticed that when children answered items incorrectly, they tended to give the same wrong answer. He inferred that the children must have approached the problems methodically, only the method differed from that of adults. After altering the testing methods to include the exploration of children's answers and devising many probes of his own, he set about determining the intellectual organization of what he eventually conceived as four broad stages of development, each embodying a progression toward increasingly flexible, systematic, and complex thought: sensorimotor, preoperational, concrete-operational, and formal operational.

During the sensorimotor period, extending from birth to approximately eighteen months, intelligence manifests in action. Action develops within the period from reflexive movement to means-ends behavior that comes, by the end of six substages, to incorporate tool use, foresight, and detours ([1936] 1952). The advent of representational intelligence in the sixth substage manifests in additional ways, including deduction based upon remembered events, the imitation of events witnessed previously, symbolic play, and language. Thought now progresses to some degree independently of what is seen or otherwise directly experienced. For example, an eighteen-month-old child who sees a toy hidden in a box, then sees the box moved under a cloth, and then finds the box empty, will spontaneously search under the cloth for the missing toy, evidently having inferred that the toy left the box when the box was under the cloth (an instance of deduction). Children at this age might also imitate a funny face someone made the day before (an instance of deferred imitation) or slide a leaf along the countertop as though the leaf were a car (an instance of symbolic play). Although any of these representational activities might occur in the absence of language, language, which also depends upon conceptual connections, normally begins at around the same time.

These symptoms of nascent representational thought mark the beginning of Piaget's second broad stage, of preoperational or intuitive intelligence, which extends roughly
from two to seven years of age. Piaget found that, despite the advances it embodied, thought during this interval exhibited limitations, in particular with respect to the property of what he termed reversibility. The limitation is apparent in Piaget's best-known experiment with school-age children, his probe of what he called the "conservation" of quantity. When water, for example, is poured from a wide flask into a thin one, although adults or older children know the water level must rise, children under the age of (approximately) seven years sometimes anticipate that the water level will remain the same. Alternatively, when confronted with the raised water level after the water is poured, they may assert that the new (thin) flask contains more water than did the original (wide) flask ([1941] 1965).

By comparison, when presented with the same problem, children between seven and twelve years, normally the stage of concrete-operational thought, say the amount in response to the change. When water, for example, is poured from a wide into a thin flask, although adults or older children know the water level must rise, children under the age of (approximately) seven years sometimes anticipate that the water level will remain the same. Alternatively, when confronted with the raised water level after the water is poured, they may assert that the new (thin) flask contains more water than did the original (wide) flask ([1941] 1965).

The state of affairs had to be concrete and observable, however, whereas from roughly twelve years onward, during the formal operational stage, individuals can reason about hypothetical states and solve both abstract and concrete problems systematically, by taking account of, and if necessary manipulating, all variables pertinent to a problem. Thus, as a scientist would do, a child at this stage confronted with the problem of determining which of a series of chemicals was responsible for altering the color of a solution, for instance, would systematically vary each possible combination of liquids to isolate the necessary reaction (Inhelder and Piaget [1955] 1958).

Development through the stage of concrete operations is believed to be universal, whereas only a fraction of even well-educated teenagers from the United States exhibit formal operational reasoning when they are given the problems originally employed by Piaget. As suggested by Jean Retschitzki (1989) in a study of expert players of a popular game in the Ivory Coast, however, evidence exists that formal-operational reasoning may be employed even by members of undeveloped countries with low literacy when people participate in culturally indigenous activities in which they are expert.

Piaget characterized these tiers of development in a second way, as embodying three "Copernican revolutions" ([1964] 1968), in which children, initially "egocentric" at the level in question, gradually progressed toward the ability to take alternative perspectives into account. Although Piaget eventually retracted the term egocentric in response to its apparent misconstrual by other psychologists, he retained the substantive theses underlying it.

During the sensorimotor period of infancy, as conceived within this second scheme, children come gradually to acknowledge a self, a world, and their separation. They come to recognize, for example, that their caregivers come and go on their own and that the external world generally operates independently of them ([1937] 1954).

During the preoperational period of early childhood, children progress from an obliviousness to the perspective of others to the awareness that others may perceive things differently from what they perceive, and they anticipate the alternative perspective. Thus, for instance, whereas when an interlocutor's back is turned, a four-year-old might point to the location of an object for which the interlocutor is searching, an older child would describe the location ([1923] 1955).

Corresponding to the advent of the capacity for formal operations is an interest in abstract ideals and, according to Piaget, a progression during adolescence from the view that the world should submit to one's schemes to the understanding that one does not know everything ([1964] 1968).

Piaget believed his stage sequences extended to many areas of cognition, including logical thought and children's conceptions of objects, space, time, causality, number, chance, and probability, as well as aspects of perception and memory. He perceived their manifestations also in areas of social life, especially morality. Corresponding to the progression he observed toward concrete operations, for example, he documented the emergence of an understanding of and interest in social rules and an appreciation of their purpose in regulating people's relations and protecting their welfare. He also documented a trend from the negative moral valuation of people whose actions produce bad outcomes to the negative valuation of those whose intentions are bad ([1932] 1965).

In delineating the myriad developments he did, Piaget ascribed greater importance to the sequence of developments he described than to the uniformity of development across areas of activity. He believed, however, that the capacity for more primitive types of reasoning remained in all areas throughout life and, especially in the case of morality, were more evident in some individuals and groups than in others.

BASIC CONCEPTS: THE PROCESS OF DEVELOPMENT

All of the developments Piaget described resulted, he believed, from natural, spontaneous development. With
the possible exception of moral judgment, whose early stages he suggested reflected the influence of adult disciplinary tactics, the developments were not taught or otherwise prompted by the environment, which at most afforded (or limited) opportunities for growth. He contended, moreover, that the advances he charted arose through feedback from children's own action, as opposed to from the maturation of innately given abilities.

Piaget was sufficiently convinced of the potential of the mind to construct itself that he believed the entire series of developments he described evolved from a starting point of only reflexive action and the "invariant functions" of assimilation, accommodation, and the progressive storage of their results, which Piaget called organization. Merely by sucking, grasping, listening, and looking—initially reflexively—and repeating these behaviors, as followed from the inborn tendency to repeat experiences (the most primitive manifestation of assimilation), the resulting chance effects would eventually bring about change in the actions. Further changes would follow from there, until individuals reached the final equilibrium of adult forms of thought ([1936] 1952).

CRITICISM OF THE THEORY

Piaget's studies of children have been replicated worldwide, in both developed and undeveloped countries. Many have also extended his sequences to domains he did not investigate, such as attachment relations in infancy and friendships during childhood.

The theory has also been challenged by researchers who, after modifying the measures Piaget used to assess the abilities he investigated, have produced results the researchers believe attest to children's grasp of mature concepts at an earlier stage than Piaget specified. Some of this work appears in reviews by Paul Harris (1989) and John Flavell and colleagues (2002). The researchers assert that the results warrant a different model of development in which, rather than gradually developing the concepts in question, as Piaget described, children begin development in possession of the concepts' essentials and progressively "access" the essentials in increasingly reflective thought and over ever broader areas of application; Paul Rozin lays out a version of the model in "The Evolution of Intelligence and Access to the Cognitive Unconscious" (1976). According to the general view, younger children falter on Piaget's tasks not because they lack the concepts under examination, but because they become confused by nonessential features of Piaget's experiments. With age, the view says, as children's working memory and attentional capabilities increase, children became better able to negotiate Piaget's tasks.

Some researchers in the foregoing line have challenged Piaget's theory based not upon new experimental procedures, which most of the aforementioned studies employ, but upon naturalistically occurring behavior, a focus more in keeping with Piaget's original observations. For example, in 1973 Marilyn Shatz and Rochelle Gelman reported that, contrary to the idea that preschoolers fail to take in others' perspectives when addressing them, four-year-olds simplify their speech when they talk to two-year-olds. More recently, Debra van Ausdale and Joseph Feagin (2001) found evidence in preschoolers' social interactions of racist ideas and practices that the authors believe possible only with the "operational" thought Piaget ascribed to middle childhood.

Another line of criticism questions the cogency of Piaget's theoretical constructs independently of the data, as exemplified by works by Sophie Haroutunian (1983) and Susan Sugarman (1987a), or the formalisms he used to represent the constructs, as argued by Daniel Osherson (1974).

Few dispute Piaget's sequences as measured by his own tests. Controversy continues about the equivalence of the concepts measured by newer tests to the concepts assessed by Piaget's procedures. The two bodies of work differ fundamentally in method. Whereas the work that challenges Piaget's norms replaces his tests at younger ages, Piaget extrapolated to his sequences from developmental changes in children's behavior on the same measure at all ages he tested; the strategy dates to Piaget's days as a researcher in intelligence testing. The difference makes it difficult to render any final conclusion about the import of the apparently conflicting results (see Sugarman 1987b for discussion of this).

With respect specifically to the challenges brought by fresh observations of naturally occurring behavior, evidence can be found within Piaget's own observations of allegedly "preoperational" thought more complex than that ascribed by his account of preoperational thinking (Sugarman 1987a). Nonetheless, the particular complexities Piaget associated with "operational" thinking, in the abstract reflective thought in which he sought them, do not appear in either Piaget's or newer data. The claim that the racist ideas and practices of some preschoolers require operational thought presents the additional problem that racism bears precisely the hallmarks of preoperational mentality as Piaget originally defined it. These properties include a one-sided point of view, often based upon appearances, that does not take account of alternative vantage points, is impervious to contradiction, and consequently remains unaware of itself as a point of view. Especially in the moral domain, which, as Piaget discusses in The Moral Judgment of the Child ([1932] 1965), draws upon incompletely comprehended adult influences, thought can become rigid and nearly mystical as a result of these tendencies. Given the persistence of these charac-

PIMPS

A pimp is commonly defined as a person who lives off the income of a prostitute. More often than not, the prostitutes are female. Pimps often lure their victims into prostitution under the pretense of a love relationship, specifically targeting adolescents who have escaped physical or sexual violence at home and are vulnerable economically, socially, and sexually. Assuming the role of a “boyfriend,” a pimp might eventually suggest to his girlfriend to have sex with his friend as a favor, and eventually might resort to violence to “break her” (including beatings, death threats, rape, gang rape, false imprisonment), often also introducing her to drugs to make the person dependent on him.

Pimps might have prostitutes engage in sex work in various venues, such as brothels, escort services, massage parlors, or strip clubs. The more prestigious the establishment, the less brutal and direct is the pimp’s abuse of prostitutes. Sex workers dependent on crack tend to occupy the lowest rank of all, demanding the least pay—usually in the form of crack—and providing the most high-risk sexual services. In a way symbolic of the dependency of the prostitute on the pimp, for these prostitutes the “crack pipe is the pimp.”
Pimps

A pimp might secure the area in which a prostitute pursues customers. A pimp prides himself on “managing” all financial and economic matters prostitutes experience in their work, including marketing (finding customers) and workplace protection (controlling an area of the street from competition, fighting dangerous or nonpaying customers, or paying off police). He might also post bail for prostitutes who have been apprehended by police.

A pimp demands all or the majority of the money prostitutes generate through their work for himself. By having more than one prostitute, a pimp multiplies his income capabilities, and experienced pimps boast about the size of their “stables,” or the number of prostitutes working for them.

Ostensibly, women “trade” part or all of their income to the pimp in exchange for protection from abusive customers or those who refuse to pay, or from other pimps who might try to force them to work for them. To what extent women actively and willingly participate in a relationship with a pimp is a point of debate. Some feminists and human-rights advocates consider any sex work as sexual oppression of women and challenge the idea that someone agrees to being managed by a pimp. Their opponents argue that sex work needs to be legalized and protected. But even advocates of prostitution often request that pimping remain illegal.

A critical psychological requirement to become a successful pimp is to “learn how to reverse the pussy game.” In other words, rather than sexually desiring the prostitutes who work for him, and thus becoming sexually vulnerable if they withhold their affection from him, the pimp has to learn to subjugate his sexual desires to his financial desires. In this regard, the pimp is regarded as the ultimate hustler and manipulator.

In the social milieu of the underworld, pimps enjoy high status by exhibiting many traits of hegemonic masculinity—conspicuous consumption (fancy clothes, jewelry, accessories, cars) and other evidence of a successful economic position, control over women, and sexual access as well as opportunity. Although the pimp has enjoyed a long history as an iconic figure in certain subcultures of the United States (for example, Iceberg Slim), the pimp has become a mainstream persona only since the mid-1990s, when gangsta rappers such as Snoop Dogg made the pimp a staple of their lyrics and a persona they also try to cultivate offstage. Since then, it has become a broadly used term of approval and endearment across all youth cultures, with ever-growing appeal in commercial venues, including such popular shows as “Pimp My Ride” (Staiger 2005). But while in the racial imagination of the United States pimps are thought to be primarily African American, pimping is not limited to any particular race or ethnicity.

Notwithstanding this widespread perception of the pimp, current research reveals a more complex picture of pimps and their relationship to prostitutes. A comparative ethnographic study in Canada’s major cities found that many prostitutes do not have pimps at all, while a study of New Jersey streetwalkers found that pimps are in fact often boyfriends or husbands. Further, the emotional attachment between the pimps and prostitutes can be strong and supportive, with prostitutes sometimes lovingly referring to their pimps as “Daddy.” As the New Jersey study found, prostitutes tend to consider their sexual interaction with customers not as a form of making love but merely as a sexual transaction with instant compensation, while reserving their emotions of sexual intimacy for their sexual relations with their pimps. This factor also explains why prostitutes who are meticulous about using condoms with customers often refuse to use condoms with their pimps, as the condom is equated with sex as a commercial transaction. This semantic separation of lovemaking with the pimp versus tricking the john suggests the psychological significance of the pimp as a means to “normalize” the sexual identity of the prostitute, an emotional attachment that of course can also give the pimp additional power.

The potential for violent relationships, however, is always there, and some pimp–prostitute relationships have characteristics of battered-batterer relations on one hand or sadomasochistic relations on the other. According to the autobiography of Iceberg Slim, a legendary pimp from the 1930s to the 1950s, successful pimps “train” their prostitutes through the use of well-calculated torture. How realistic Iceberg Slim’s alleged autobiography is remains questionable, but following the popularity of this text in the United States and worldwide as a handbook on how to pimp and as a bible for the gangsta rap of the 1990s, it is to be expected that many imagine pimps and prostitutes in this way, if not practice pimping accordingly.

Another pressing issue is the growing phenomenon of human trafficking fueled by the increasing profitability and the growing divide between poor countries that send prostitutes and high-demand, wealthy countries that receive them. In this manifestation of pimping, the socioeconomic role of the pimp is tilted to the extreme of economic exploitation, where pimps subject prostitutes to brutal sexual, physical, and mental abuse to “condition” them into docility and resignation, before selling them again to other pimps or end users. In such contexts, pimps take on characteristics of slave traders, “buying” individuals “in bulk” and “reselling” them to other pimps/traffic-keurs within a relatively short period of time before finally “dumping” them if they are too sick or too old to generate further profits. This form of pimping has no traces of emotional attachment between pimp and prostitute,
except for the terror of physical and sexual violence. This phenomenon of pimping has been described for traffickers from eastern Europe.

Theoretically, pimps can also be women. The trend, however, has been that women who reap profits from the prostitution of another tend to do so in brothels, with greater formal security. These women are called madams. Often they are ex-prostitutes themselves, but contrary to common perceptions, a nineteenth-century case study from St. Paul, Minnesota, showed that these madams were little older than the prostitutes who worked in their establishments, enjoyed considerable wealth and influence in the community, and often engaged in friendly relationships with the women who worked for them. As a contemporary British study has found, their crime rates associated with prostitution tend to be substantially lower and their crimes substantially less violent than those of their male counterparts.

The violence caused by pimps, from sexual and physical abuse to torture, murder, drug dealing, and the like, constitute crimes significantly more dangerous than prostitution. While this is generally recognized, pimps tend to be charged much less frequently than prostitutes, with streetwalkers, who constitute the bottom of the sex-work industry, being the ones most likely to be arrested. Many self-help and advocacy groups have raised the charge that the laws and legal enforcement against prostitution victimize sex workers significantly more (and women more so than men) than the pimps, who are reaping the lion’s share of their profits. Responding to the growing movement of sex workers for their right to self-determination, and in the hope of eliminating the violence and crime associated with prostitution, several countries (for example, the Netherlands and Germany) have legalized prostitution. However, even in countries where prostitution is legal, pimping remains illegal. Whether legalizing prostitution in fact eliminates or diminishes the crimes associated with prostitution and the existence of pimps remains a hotly debated issue and awaits further study.

PITKIN, HANNA

1931–

Hanna Fenichel Pitkin is one of the most influential political theorists of the twentieth century. While best known for her seminal book *The Concept of Representation* (1967), Pitkin has composed several works of lasting relevance to the study of politics. She has shed light on such diverse topics as democracy, justice, gender, action, and the tension between political philosophy and political theory.

In *The Concept of Representation*, Pitkin utilizes the methods of linguistic analysis, developed by Oxford philosophers such as J. L. Austin (1911–1960), to focus on representation as a concept rather than a set of actual practices. She defines *representation* ideally as “re-presentation, a making present again” (1967, p. 8), but then moves on to show how this meaning has been distorted and contorted throughout the history of modern philosophical discourse. Every attempt to capture the complexity of the concept misleadingly conveys part of the meaning of representation as if it were the whole meaning. Pitkin surveys the various theoretical approaches to the term *representation* and finds them all lacking, including the authorization view, expressed by Thomas Hobbes (1588–1679); the trustee theory, expressed by Edmund Burke (1729–1797); and the liberal view, associated with James Madison (1751–1836), among others. Each vision is shown to be incomplete by the central paradox of representation—that is, the competing demands of the representative and the represented. Pitkin aims to preserve rather than to reconcile this paradox, and her book culminates in the recommendation that citizens safeguard both the capacity of the represented to authorize decisions and the capacity of the representatives to act independently.

Pitkin’s book has been a touchstone for subsequent work in the area of representation theory. Some contemporary scholars, however, find Pitkin’s insights to be anachronistic for a globalizing world in which practices of representation seem to stretch beyond the boundaries of the nation-state (Mansbridge 2003). Furthermore, scholars sensitive to issues of diversity and cultural heterogeneity have highlighted the ways in which every representative formation can obscure or suppress minority voices (Young 2000).

In many ways, the lasting relevance and importance of Pitkin’s early work has overshadowed her subsequent development as a thinker and theorist. In 1972 she further articulated her interest in conceptual analysis as a fruitful method of political philosophy through an examination of the late work of Ludwig Wittgenstein (1889–1951). She pays close attention to Wittgenstein’s central notion of “forms of life,” the matrices of human behavior that define the contexts in which a discourse acquires meaning. For Pitkin, political philosophy should proceed to analyze
these contexts to enhance our conceptual clarity on terms such as justice, membership, and action. Political theory, on the other hand, is concerned with advocating a change in our current conceptions, as the contexts in which we live and the needs of the human community transform through time.

Pitkin’s *The Attack of the Blob: Hannah Arendt’s Concept of the Social* (1998) exemplifies her recommended trajectories for both political philosophy and theory. She explores Hannah Arendt’s (1906–1975) use of the *social* through contextual and psychobiographical analysis, and discusses the ways in which Arendt’s concerns for action are compromised by a residual fear of social conformity. In the end, Pitkin implores her readers to discover ways in which they can become more reflective and critical as agents and actors in the world. In so doing, she echoes concerns born with her 1967 book, and reveals herself ultimately as a committed theorist of democracy.

**PLANNING**

Planning represents the process of looking into the future, establishing something out there, creating a vision of a future state of affairs, and determining means of actualizing that state. A plan is something one intends to do or achieve, as when someone asks, “Do you have any plans for the weekend?” As a construct, a plan may mean activities that have to be performed to achieve something (objective). Plans therefore are predetermined, preceding action, and constitute programs of activities (means) considered valid for achieving predetermined aims and objectives.

**TYPES OF PLANNING**

Planning can take place in a variety of areas, for plans take varied forms: policy choice, manpower plans and incentive strategies, community action plans, site plans, comprehensive plans, building plans, economic development plans, disaster containment plans, housing and community development plans, and transportation plans, among others. However, urban planning has received attention in academic discussions perhaps because of its potential for improving the welfare of people and communities as well as the added impetus given to it since the nineteenth century by the formalized disciplines of architecture and engineering. Thus planning has tended to combine rationality and stylistic approaches to solving community problems by means of physical designs. Urban planning, city planning, regional planning, or community planning are concerned with ordering and designing human settlements with a view to creating more convenient, healthy, and aesthetically pleasing places for people.

Planning generally is people and community oriented. For instance, planning for economic development is vital to the process of building sustainable community. Housing and community development planning is concerned with creating accessible and equitable communities, sensitizing people to community and development issues, and generally seeking to develop strategies to address the needs of the homeless and the handicapped. Transportation planning also tends to show similar concerns for people and communities as it aims at revitalizing suburban commercial corridors to improve accessibility and mobility and, importantly, strike a balance between community needs and the interests of transporters.

Planners construct a broad vision of the community or help communities identify their goals or create a particular vision. They develop strategies by which communities can accomplish their goals and vision. They actively participate in the implementation of plans and monitor and coordinate the work of several groups of people.

THE PLANNING PROCESS

On plans and planning, Henri Fayol wrote “‘The plan of action is, at the same time, the result envisaged, the line of action to be followed, the stages to go through and the methods to use” (Fayol 1949, p. 130). George Steiner observed that planning is “a process that begins with objectives, defines strategies, policies and detailed plans to achieve them” (Steiner 1969, p. 20). It follows therefore that the planning process has three distinct phases, namely, definition of basic objectives and goals; developing strategies and means (or strategic plans) and policies to implement objectives; and developing detailed tactical and operational plans, such as work procedures and practices, time schedules, and budgets.

Planning, no matter in what area it takes place, generally follows this characteristic pattern. The first and basic aspect of planning is setting objectives. While it is possible for individuals and organizations to have goals and objectives, it is equally possible for them not to have any. Peter Drucker highlighted the importance of objectives: “Few companies have any clear idea of what their mission is and that is one of the major causes of their worst mistakes.... Managers have no feeling for what the company is really good at and conversely what it is not good at” (Drucker 1954, p. 4). Aims and objectives are necessary not only to ensure effective performance by focusing energies, time, and other resources but also to ensure that strategies are related to objectives. Goals and objectives vary, however, and depend on the planning area and institution concerned. Common institutional goals include profitability, growth, market share, innovation, survival, social responsibility, worker and employee welfare and development, service to customers, and provision of public services.

Planning is also concerned with decisions about methods, that is, about means or strategies for achieving identified aims and objectives. Strategic planning (or developing strategies and policies for achieving objectives) describes processes involved in producing plans, often called strategies, that identify the basic objectives and concrete actions necessary to implement them. This aspect of planning calls for auditing of the planning environment to identify needs, constraints, opportunities, and the organization’s internal strengths, weaknesses, resources, and capabilities.

The experience of California Union Bank provides apt example of a firm scanning its rather crowded competitive environment. When Harry Volk accepted an offer to become president of the bank in 1957, he surveyed the banking industry and perceived a vigorous race to create more retail or consumer-oriented branches. Rather than join the race, he decided to pursue a different strategy. Volk had observed that no bank concentrated exclusively on businesses, particularly fairly risky business loans. He reasoned that if he charged higher-than-normal interest rates on weaker credit risks, it was possible to suffer higher-than-normal loan losses and yet have a profitable business. Consequently, Union Bank opted to pursue a strategy of becoming a wholesale- or business-oriented bank.

Another aspect of planning is determination of the manner in which plans must necessarily be carried out. This is essentially a matter of conduct generally governed by such written documents as mission statements, policy statements, customer charters, and the like. Policies provide guides to decision-making, reflect company objectives, and generally guide managers and employees toward objectives in situations where judgment and discretion are required. However, conduct may also either be determined by influence or by informal standards that lie beneath organizational behavior.

The next phase preceding action in the planning process is developing tactical plans, which involves making specific commitments and providing details for methods (work practices and procedures), money (budgets), and time (time schedules). While policy provides guides for deciding, procedures provide guides for doing, for concrete actions. Procedures refer to methods of carrying out activities and might prescribe steps to be followed in doing work a kind of checklist for action. Procedures produce programmed responses to organizational problems and apply mainly to routine repetitive work.

PUBLIC-SECTOR PLANNING

Planning in the public sector is essentially embodied in public budgets, so public-sector planning emphasizes project-based financial plans. Because plans are problem-solving mechanisms, they design solutions to public-sector problems. The process in the public sector presents a distinctively different scenario from private-sector or business planning. While mathematical optimization models and computer formulations and simulations may be developed under the philosophy of obtaining “the answer,” that is, the best or optimal solution for business problems, such models, including multiobjectives models, when applied to public-sector planning, may not be useful because there is a multitude of local optima and because important planning elements are not captured in the formulations. The omitted elements may actually imply that the optimal planning solution lies within the inferior region of multiobjective analysis rather than along the noninferior frontier. The choice of action, selection of public programs, or decision option may be far from the best, what is most rational, or what makes an economic sense, but it remains a political choice. The roles of these optimization methods have been to generate planning alternatives and to facilitate their evaluation and elabora-
Planning

Business planning is relatively new to public-sector and nonprofit organizations. Approaches to business planning in provincial, municipal, federal, or board-governed organizations are different from those in the private sector, although the language and concepts remain the same. The emphasis remains on establishing the vision, goals, strategies, and performance measures for high-performance organizations.

Such plans develop strategies for performance measurement, create benchmarks, and set standards. They may also include implementation strategies with emphasis on service excellence and must necessarily involve people in the decisions that affect them. However, many rational planning models applied in the public sector appear to focus on efficiency objectives and suffer from two lingering limitations: failure to consider equity or distribution of income and the empirical limitation of calculating costs and benefits. This has meant that achieving planning’s intended roles in the public domain may require the use of several models as well as new types of optimization formulations and modified algorithms and computer codes. Optimization models are important because they help generate planning alternatives and facilitate comparison between them. Thus in the public sector it may be desirable to use several different models to aid the planning process.

Because plans are strategic instruments for goal attainment, their nature and form tend to be determined by the type and nature of objectives and goals established. While goals tend to differ from one individual and organization to another and while individuals and groups generally operate under varying conditions, the effectiveness of plans and planning appears to depend on the total planning situation, consisting of several sometimes complex variables, such as the knowledge, skill, and expertise of planners, available resources and technology, and the nature of the environment, among others. It means that plans must be related to objectives and adapted to the circumstances of the planning institution. Therefore plans that enable organizations to cope with relatively stable conditions will differ in significant respects from plans that suit relatively unstable conditions. For instance, extrapolative planning may be appropriate for stable conditions, enabling forecasts of revenue and expenditure to be made based on current conditions that are assumed to remain unchanged from the previous planning period. While its major purpose may be to ensure control over costs and legality of action, extrapolative planning is unsuitable for long-range planning and incapable of dealing with turbulence and the constraints of unstable conditions. On the contrary, unstable conditions, where there are uncertainties and where the environment is characterized by turbulence and complexities, warrant a rational comprehensive planning approach able to address long-term goals and contend with the various environmental forces. Planning, programming, and budgeting systems, one approach often used in the public sector, offer great potential for dealing with the present-day world of uncertainties. It is an integrated planning-budgeting system that is program based and relates expenditures to performance and outcomes.

Public-sector planning calls for access to budget information and the ability to understand that such information is capable of promoting public involvement in and scrutiny of the budget process. Public access to government policy initiatives, priorities, and implementation can promote popular participation. Public planners therefore necessarily need to look out for and respond to forces from the popular sector if social rationality in the public planning process is to be achieved. While the aim of rational public planning may be economic prosperity, the elimination or reduction of poverty, and the provision of public goods, good health, environmental sanity, and security, or in a nutshell, provision of general happiness, to exclude the public in this process totally contradicts the requirements of long-term comprehensive planning, which calls for active participation, cooperation, and the support of all stakeholders and clientele groups in society. In a democratic society, a theoretical and empirical if not political question has often remained: Who determines or takes part in determining what constitutes general interests? The public will probably remain indispensable in answering these questions.

Public access to information on public policy issues recommends itself for effective national comprehensive planning because it guarantees both government accountability and civil society participation in the budget process. This enables planners to use feedback arising from internal and external sources to bring about necessary adjustments in plans and, through public criticism or external performance evaluation, to remain focused.

PLANTATION

Often defined as a "total institution," even as a prison camp, the plantation has been represented as both a type of social institution and an agricultural organization. The historical significance of this socioeconomic complex stems largely from its function in capitalist agricultural production, where it has been considered instrumental both in the creation and persistence of economic underdevelopment of those tropical areas where it dominated, and in the industrialization of northern Atlantic economies. In his influential text *Persistent Poverty* (1972), agricultural economist George Beckford, building on the seminal ideas of Lloyd Best (1968), argued that while the plantation incorporated all regions where it dominated in the larger developing world economy, as a type of economic organization it did so unevenly, driving the modernization of regions of the northern Atlantic, particularly Britain, at the expense of those in the south, including the U.S. South. However, other scholars, notably Robert Fogel and Stanley Engerman (1974), countered this perspective and held that U.S. southern plantation economies were a variant of capitalism. Such plantations, they argued, were highly productive and profitable, and the U.S. South's comparative advantages as an agricultural zone accounted for its limited or nonindustrialization.

The plantation economies of the Americas incorporated thousands of mainly African laborers, unskilled and enslaved, both free and indentured, who produced for the home and/or export market, as occurred in the U.S. South, the Caribbean, and South America. They labored on both small plantations as in the U.S. South with enslaved labor locked into paternalistic or overtly coercive relationships and large-scale, highly regimented, exploitative factory-like labor-force control. Plantation agriculture thus bespoke a peculiar mix of capital and labor processes. Consequently, debates emerged over its economic modus operandi and labor organization. These "modes of production" debates, prevalent during the mid-1970s through the 1980s, turned on whether slaves were proletarians or an in-between labor form, and whether the plantation was capitalist or not. While no scholar disputed the triangulated relationship between plantations and areas of the proto-industrializing Atlantic, differences emerged about how to characterize its relationship to the emergent capitalist economic system. Generally, several analysts saw the plantation as articulated with capitalism but distinct from it, while primarily non-Marxists viewed the emergent global market (then mercantile) as the critical defining element of the capitalist world system, given slavery's facilitation of wage labor and the circulation of commodities primarily from then-emergent industrialized countries. This view was particularly prevalent among world-system theorists such as Immanuel Wallerstein (1979), who stressed relational historical developments.

Hotly debated also were questions centering on the cultures and personalities found on plantations. For example, Eric Williams (1944) saw racialization as an outcome of plantation slavery. Others averred that plantation slavery was itself a product of racialized thinking. These provocative positions were joined by questions about the social consequences of slavery's economic and racial divisions. Comparing Latin America and the U.S. South in his influential 1959 text, *Slavery: A Problem in American Institutional and Intellectual Life*, Stanley Elkins compared the "closed" authoritarian system of the plantation to Nazism's psychic destruction and concluded that plantation slavery resulted in a psychological stripping of the slave, thereby producing an infantile Sambo mentality or personality. Elkins's Sambo-type personality resonated with stereotypical representations of blacks found in earlier American classics, such as the films *Birth of a Nation* and *Gone with the Wind*, the latter adapted from Margaret Mitchell's 1936 best seller. In the former, freed and out-of-control Sambos visited disorder and chaos upon a highly racialized, gendered, and segregated South ostensibly preoccupied with protecting the virtues of white womanhood, while in the latter, blacks were stereotyped props for a melodramatic Southern romance. But these representations of the docile slave were swiftly undercut by other studies documenting modes of resistance that spelled agency rather than passivity, and later there emerged other perspectives that complicated those notions as well.

Eugene Genovese's *Roll, Jordan, Roll: The World the Slaves Made* (1976) would shift the discussion toward more detailed research on the sociocultural nature of plantation life and its impact on the U.S. South. In this seminal work, Genovese explored the master–slave relationship, arguing that masters' and slaves' transactions were paternalist in nature. For him such a hegemonic relation yielded a tacit realization and acceptance by both slave and master of their symbiotic roles within the slavery complex. In other words, slaves and masters realized their dependence on each other, and the so-called exploitative relation stressed by other analysts was shaped essentially by familial practices that tempered the incidence of slave revolts.

Several scholars have contested Genovese's conclusions and highlighted the need to distinguish between
physical domination and hegemony, thereby undermining his romanticization of the planter class and his thesis of slaves’ willful participation in the plantation-slavery complex. Moreover, analysts point to the pitfalls of reading slaves’ practices within the slave system from generalized conclusions culled from too few planters in a large-scale plantation-slave complex that covered the U.S. South. Such perspectives suggest that dependent connections do not negate the incidence of exploitative relationships, nor do they prohibit the development of spaces for creating and articulating futures that are different from those the planters may have envisioned. Subsequent scholarship, which has focused on strategies of maneuver and on processes of culture building by the enslaved, tends to bear this out.

**PLANTATION ECONOMY MODEL**

The theory of plantation economy and society has been developed to explain the experience and evolution of societies subjected to European-controlled sugarcane production by an enslaved African labor force and later by indentured Asian laborers (mostly Indians). As the historian Philip Curtin observes, “The plantation complex … ultimately stretched from Rio Grande do Sul in south eastern Brazil to the Mason-Dixon line and it had outliers in the Indian Ocean islands of Reunion and Mauritius” (Curtin 1998, p. xii).

The plantation economy model posits that plantation slavery and specialization in export of primary commodities has marked the evolution of the societies in which it existed. The plantation economy theorist Lloyd Best hypothesizes, “The legacy of institutions, structures and behaviour patterns of the plantation system are so deeply entrenched that adjustment tends to take place as an adaptation within the bounds of the established framework” (Best 1968, p. 32). The Caribbean economist Norman Girvan contends that the transnational corporation (TNC) is an institution that exists within the “rules of the game” of the plantation economy. He points out that the historic continuity of foreign ownership, terminal stage of production, limited domestic linkages, repatriation of profits, and persistence of the incalculability of value flows with transfer pricing by TNCs are similar to slave plantation–metropole flows.

The plantation school is not fatalistic but perceives the need to understand the grip of the founding institution of the plantation in order to remove its stranglehold on the dynamic for change within the interstices of the system. The role of the Maroon, or runaway slave, culture of resistance and non-plantation production by the peasantry, for example, is central to transformation of the plantation economy. Plantation economies continue to reflect the historic legacy with plantation-type enterprises operating in primary, natural resource sectors, such as oil, gas, bauxite, bananas, sugar, and tourism. Nontraditional producing sectors compete with these export sectors and with import sectors. Fiscal, monetary, exchange rate, and industrial policy do not favor such nontraditional, residency-type activities. The term *residency sector* was developed by the plantation economy theorists to describe non-plantation production that sprang up after the end of slavery.

A subtext is the contribution of plantation economies to the industrial transformation of the slave-owning metropolitan countries themselves. Curtin notes that “the Europeans who ran the (plantation) complex learned a great deal from the experience—in ocean shipping, tropical agriculture and economic management at a distance. All this is a part of the background of the industrial age” (Curtin 1998, p. 204).
Plantation economy theory has become diffused in a range of courses offered at the University of the West Indies, including economics, sociology, and political science. Many economists incorporate plantation economy theory in an evolving theory of Caribbean economy and society. These economists include Michael Witter, Mark Figueroa, Claremont Kirton, Vanus James, and Dennis Pantin of the University of the West Indies and Eric St. Cyr. The plantation economy model differs from the Arthur Lewis model of transformation by its focus on the potential within residuary sector peasant production. Lewis emphasizes dismantling the traditional sector and replacing it with a modern sector. Some adherents of the plantation economy share the Guyanese historian Walter Rodney's concept of the underdevelopment of both Africa and the Caribbean, while others, notably Lloyd Best, argue that Rodney's view is static and mechanistic in nature.

Critics of the plantation model include Adlith Brown and Havelock Brewster, who contend that the school has not produced a theory but rather a recounting of the history of the Caribbean. Trevor Sudama questions the historic accuracy of the model when applied to Trinidad and Tobago. Denis Benn, Thomas, and Pantin raise questions on the model's method and theory.

**PLATO**

**427–347 BCE**

Plato was born in Athens in 427 BCE just as the Peloponnesian War between Athens and Sparta was beginning. His mother was related to one of the oligarchs who ruled Athens after the Spartan victory in 404 BCE, and his father died when Plato was very young. The most important shaping influence in Plato's early life, however, was the philosopher Socrates (469–399 BCE). Plato was among the young men of Athens who regularly engaged Socrates in dialogue and who took the Socratic challenge to “know thyself” very seriously. Plato, then twenty-eight, was present at the trial of Socrates, an event that clearly made a deep and lasting impression on Plato and which is reflected in all of his work. Socrates is widely regarded as the hero of the Platonic dialogues, a literary form that Plato preferred for most of his works. Following Socrates' death, Plato traveled throughout Italy, Sicily, and parts of northern Africa before returning to Athens, where he founded the Academy in about 387 BCE. Among Plato's pupils there, for twenty years, was Aristotle (384–322 BCE). Late in life, Plato traveled to Syracuse to educate and inspire a new young king, Dionysius II, though the attempt ended in failure. Plato died in Athens in 347 BCE at the age of eighty-one.

Among the more famous of Plato's dialogues are the *Apology, Crito,* and *Euthyphro,* on the trial and death of Socrates; the *Gorgias,* which explores the way of life of the sophist; the *Symposium,* which focuses on love and beauty; the *Phaedrus,* on rhetoric; and the *Timaeus,* a study of cosmology. Other dialogues of note that are still widely read and studied today are the *Meno, Protagoras, Phaedo,* *Thaetetus,* and the *Sophist.* All of these deal in various ways with Plato's famous theory of *forms,* according to which aspects of the physical world, because subject to decay and death, are inferior to eternal forms such as the true, the good, and the beautiful. But Plato's most famous dialogues, and those that continue to shape international discussion and research in the social sciences, in some measure at least, particularly in political science, are the *Republic,* the *Statesman,* and the *Laws.*

The *Republic* is considered one of the great works of world literature. It is often referred to as an example of utopian literature, which sketches an ideal *polis,* or city-state. Such a view distorts, however, what Plato clearly intended as an exploration of what human beings mean when they appeal to justice and to good rule or government. Similarly, the *Republic* is frequently summarized as an appeal for the rule of philosopher kings. This too obscures, at a minimum, Plato's belief in gender equality among *philosopher rulers,* not necessarily *kings.* Like any classic work, it is difficult to condense and summarize Plato's *Republic.* But there are key aspects that may be
sketched along the following lines. At the center of Plato’s political theory is a concept of the cardinal virtues. These virtues are moderation, or temperance, courage, wisdom, and justice. Following a procedure according to which the state (city-state) is the human person “writ large,” Plato examines the cardinal virtues both with respect to the individual person and with respect to the larger city-state. Ultimately, a just society for Plato is a society of just persons. And individuals are just according to their capacity with respect to each of the cardinal virtues. Another important concept in the Republic is the three waves, which refer to perennial issues in all societies at all times. These waves represent the issues of gender, property relations, and who should rule. In the dialogue, Socrates argues on behalf of gender equality; for a community of goods and spouses for the guardians of the polis, a group further divided according to warriors (auxiliaries) and rulers (philosopher rulers); and for the rule of philosophers. A full measure of justice is possible for Plato only when philosophers become rulers or rulers become philosophers.

Perhaps the most famous passages in the Republic are those that present the allegories of the divided line, from Book VI, and the cave, from Book VII. According to the divided line, human consciousness develops well or poorly according to a progression from imagination, to belief, to understanding, to reason based on consciousness of the good. This same progression is illustrated in the famous cave allegory, where we must imagine human beings chained and facing a cave wall, see them believe in the images projected on that wall from a fire behind their backs, understand that there might be more to reality than what such images suggest to the cave dwellers, and have the courage and capacity, unlike most of those in the cave, to turn around, see the drama to our backs, and theirs, and make our way out of the cave to a transcendent reality that, for Plato, must ultimately inform human reason. These allegories come toward the end of the Republic and summarize and condense what is explored through dialogue in the previous five books (chapters). Toward the end of the dialogue, Plato presents his thoughts on declining forms and censorship. According to the first, regime forms decay over time, such as from aristocracy (rule of the virtuous), to timocracy (rule of those who love honors), to oligarchy (rule of the wealthy), to democracy (rule of those who love freedom), to tyranny (rule of the lustful despot). The final book, Book X, explores the role of the artist in society, among other topics, and the need for some form of censorship.

The Statesman and the Laws represent significant departures from Plato’s views and style of presentation in the Republic. In the Statesman, for example, an outsider from Elea takes the place of Socrates as the primary spokesperson and the dialogue form is all but abandoned. More significantly, Plato emphasizes a rule of law, or legal codes, as preferable to the rule of philosophers. This shift of emphasis in the Statesman puts Plato more in the tradition of constitutional democracy, with its emphasis on well-constructed constitutions and institutions, characteristic of modern and postmodern approaches to the science of politics. Yet, in the Laws, among Plato’s last works, which otherwise places a similar emphasis on the need for good laws, one encounters a nocturnal council that would be the final authority in the city-state. Many critics point to this dimension of Plato’s work to support the idea that Plato was ultimately something of a totalitarian.

The twentieth-century philosopher Alfred North Whitehead (1861–1947) once famously observed that the European philosophical tradition could be characterized as but a “series of footnotes to Plato.” Though his influence is not as great in the modern social sciences, there is continuing debate, especially among theorists within the discipline of political science, regarding Plato’s insights on the role of intellectuals in society; the role of government in promoting excellence, or virtue; the educative function of the state; gender relations; property relations; the role of religion in the state, if any; and the perennial question regarding who should rule and why. And these are but a few of the modern issues regarding which Plato’s works continue to inspire creative approaches. Some modern scholars, most famously Karl Popper (1902–1994), see in Plato’s political theory the seeds of modern tyranny and closed societies. Others, such as John H. Hallowell (1913–1991), Eric Voegelin (1901–1985), and James M. Rhodes, see a more balanced and humane approach to the study and practice of politics. Because of his depth of insight and his creative approach to the perennial issues of human beings in their social and political dimensions beyond temporal and cultural considerations, Plato and his legacy will continue to be debated among scholars in all of the modern social sciences into the distant future.

PLUMBING
The progress of a society may be judged by the way in which it disposes of its human waste material, and thus by the quality of its sewerage system (Mumford 1961, chap. 8). In the ancient world, the Greeks and Romans put great emphasis upon town planning. Roman cities were famed for their sewers, drains, aqueducts, paved streets, and roads. Domestic plumbing ranged from marble bathrooms with under-floor heating and indoor toilets in upmarket villas to basic latrine provision for the Roman army, as found, for example, alongside Hadrian’s Wall in northern Britain (Greed 2003). Following the decline of the Roman Empire, waste disposal returned to more primitive methods. Most ordinary people used an outdoor “privy,” while nobles often had an “indoor” toilet built out from the wall of their castle, hanging over the moat. In the Christian West during the Middle Ages, indoor plumbing, or for that matter personal hygiene and privacy, were not highly esteemed marks of civilization or progress, although washing and bathing, and bathhouses, were given higher priority in the Muslim East (Bonneville 1997).

In urban areas, the emptying of chamber pots straight into the street, and the accumulation of piles of human waste, resulted in disease and an unpleasant urban environment. Night-soil men were often employed to collect excreta, which was spread on the fields as fertilizer. Although Sir John Harrington had developed an indoor flushing toilet for Queen Elizabeth I in 1596, it was not until the rise of mass industrialization and urbanization in the nineteenth century that domestic toilets were mass-produced in northern England. Flushing technology was improved through the efforts of inventive manufacturers such as John Shanks, George Jennings, Alexander Cummings, and Thomas Crapper in the United Kingdom (Reyburn 1969) and Thomas Maddocks, John Randall Mann, William Campbell, and Henry Demarest, among others, in the United States (Palmer 1973). Early toilet manufacturers were generally companies that had first made their name in the manufacture of china and earthenware. Such English companies as Minton, Twyford, and Doulton adapted their production processes to make porcelain toilet bowls and pans. Toilet design was based upon the “sit” rather than “squat” mode of excretion (which required nothing more than a hole in the ground). The sit approach required a specific and highly marketable consumer product, the “pedestal” toilet, along with all the plumbing fixtures, such as taps (faucets), cisterns, basins, and fittings that together made up the “bathroom.” Interestingly, urinals for men, although a common feature of public toilets, are not generally a feature of private domestic bathrooms. These artifacts were exported from Britain to the rest of the world as a sign of modernity and Western progress, and were rapidly adopted for fear of being seen as “backward” or “dirty,” in spite of the fact that the majority of the world’s population squats when eliminating waste, a position that is ergonomically more healthy and efficient.

Compartmentalization of production was marked by separate metal-manufacture companies specializing in lead piping, plumbing fixtures, and other nonporcelain components. Nowadays, international toilet companies such as Armitage Shanks, Ideal Standard, and Geberit have diversified to offer a wide range of toilet technologies and materials. Synthetic materials now predominate; piping is made of plastic and the “porcelain” is more likely to be polymer. Old and widely used lead piping has been condemned as a potential cause of poisoning. (Plumbing gets its name from plomb, the medieval word for lead, as plumbers were essentially lead workers.)

While in the past, mains drainage and indoor plumbing were a sign of modernity, today people want “designer” bathrooms, luxury fixtures, power showers, fitted kitchens, and the latest technology. There has been a “restroom revolution” in Asia in particular, with companies such as Toto producing complete prefabricated bathroom units for the Japanese housing market, all the components being made together. Colored polyester resins, modern plastics, and marble and granite composites feature strongly in these modern bathroom modules (Greed 2003). Likewise, modern automatic public toilets are fully integrated, prefabricated systems that often use stainless steel and pathogen-resistant polymer materials. However, user-end toilet innovation must be matched by provider-end infrastructural sewerage system provision. The functionality of domestic toilets is dependent on there being a working sewerage system to take away output. Alternatively, the output from a luxury bathroom, as is the case in some affluent areas in developing countries,
might end up in a cesspool under the house for collection by traditional night-soil operatives. Alternatively, as in some parts of the Americas and Australasia, even upmarket private houses are not served by a municipal sewerage and drainage system, and depend upon their own cesspits, generators, and water tanks.

Both public and domestic toilet design is becoming increasingly technologically driven, with automatic flushes and sensor-controlled washing-and-drying facilities becoming commonplace. In parallel, environmental sustainability requirements to save water have resulted in a range of dual-flush cisterns, waterless urinals, and human-waste recycling innovations. High levels of toilet provision in every home, along with highly developed sewerage systems, are no longer necessarily seen as signs of progress and economic development. Such assumptions are now being questioned. Many parts of the world are not economically or environmentally in a position to build modern, expensive water and sewerage systems; it is not a high priority. Water is becoming an increasingly expensive and scarce resource; some see it as “the new oil” in terms of future geopolitical tensions. Far from being a sign of economic development, many see the emphasis upon water-based sewerage systems and flushing toilets as old fashioned, colonial, and unsustainable. Instead, new, more sustainable solutions are being developed, especially within prosperous advanced Asian countries that can afford such research. Such systems will incorporate the most modern technological and scientific advances in the fields of engineering, pathogen control, and urban governance (Chun 2002; Mara 2006).

**PLURALISM**

Pluralism denotes more than one or two of anything and is contrary to monism, or the view that there is only one kind of a thing. *Pluralism* refers to a philosophical approach to the world as well as a theory of political and social power and, finally, to an empirical and normative focus on plural groups and group-based identities. Pluralism is central to liberal democracy in that it assumes that a diversity of views and identities, or a plurality of power centers, is essential to ensure democratic outcomes.

Contemporary debates over social and political pluralism tend to center on issues of identities in the context of multiethnic, multiracial, and multi-religious societies. This sense of pluralism is discussed in greater depth in the section below. Earlier theoretical formulations of pluralism reflected an evolving notion of competing interests in a democratic society and the role of non-state associations.

**BRITISH AND AMERICAN PLURALISM**

In twentieth-century Western thought, pluralism has at least two dominant strands. The first found expression in works of British political philosophy such as those of Frederic William Maitland, John Neville Figgis, G. D. H. (George Douglas Howard) Cole, and Harold J. Laski, as well as in the work of the German theorist Otto Friedrich von Gierke. The unifying theme of these works was the plurality of associations and groups of various kinds that operate independently of the state but are vital for a functional government. The argument was that centralized power in the state ought to be lessened or “pluralized” to meet the needs of citizens in a free society. In order to preserve liberty it was preferable to disperse state power among a variety of distinct and functionally autonomous groups that could better reflect the specific and diverse interests of citizens. The English pluralists rejected the sovereignty of the state but differed in their conception of the relationship between citizens and the state, with some arguing that the state is composed of groups rather than individuals and that belonging to the state is mediated through membership in other groups. These thinkers generally considered the ideal to be a limited and constrained state with a proliferation of free associations. World politics in the post–World War I era led to a resurgence of interest in a strong and effective state, thereby weakening the pluralist argument.
American theorists of pluralism shared an interest in the multiplicity of voices acting upon the state but focused on competing interest groups or pressure groups and their efforts to exert influence on the state. Notions of pluralism and its contribution to democracy originated in Alexis de Tocqueville’s *Democracy in America*, in which Tocqueville argued in part that democracy depends on a plurality of secondary associations outside of the state that prevent majoritarian democracy from becoming tyrannical. Particularly since the 1950s, American pluralists have used theories of pluralism to describe a model of minimum democratic competition for influence and office. The role of the state in this view is as something of an arbiter, seeking balance among semiautonomous, often opposed and self-interested interest groups.

One prominent pluralist, Nelson W. Polsby, described American society in 1980 as a collection of “hundreds of small special interest groups, with incompletely overlapping memberships, widely differing power bases and a multitude of techniques for exercising influence on decisions salient to them” (p. 118). American theorists argued that U.S. society was differentiated and fractured into many interest groups. One of the most influential thinkers in this group was Robert A. Dahl, whose work reflected an interest in “a plurality of relatively autonomous (independent) organizations (subsystmes) within the domain of a state” (Dahl 1982, p. 5). A democracy can be called a “polyarchy” if it meets certain specific conditions, especially that it contains plural centers of interest, each of which has some influence on policy making, and that no group has a monopoly of influence. Particularly relevant to the discussion below, Dahl and other pluralists argued that pluralism of identity (race, ethnicity, religion) is generally a feature of less competitive political systems, while pluralism of interests is a feature of a democracy. Dahl also posited that a democratic society is stronger if it is made up of citizens with crosscutting identity cleavages (rather than reinforcing cleavages), which reflect common interest on some issues and opposing interest on others. This means that a democratic society is one in which a broad array of issue-oriented movements draw together new constituencies that cut across identity lines.

Pluralism in this sense also stands in contrast to corporatist politics. Pluralist interest groups are made up of multiple associations focusing on a single interest issue, and the groups are voluntary, decentralized, and separated from the government. Corporatist politics is generally more organized and is characterized by a single association for each societal interest, typically with compulsory and universal membership and with central organization. For pluralists like Dahl (1998) the associations should be relatively independent and autonomous. In all respects, pluralists focus on power dispersal as a check on all centers of power, including the state.

Critics of American pluralist theory have challenged the ideal of pluralism as well as the empirical fact that such a process operates as it has been theorized in the United States. They point to the systematic inequality among interest groups that runs counter to the pluralist vision of equal and competing associations. For instance, critics such as C. Wright Mills have argued that American politics is dominated by an economic elite and that a discussion of a mere plurality of associations does not account for the hierarchies of power present in political life. In 1970 Peter Bachrach and Morton S. Baratz highlighted the importance of nondecision-making processes, those individuals or groups that seek to limit decision-making to relatively uncontroversial issues, thereby influencing political decisions in significant ways. Their work pointed to the manner in which political systems are characterized by inequality that tends to persist over time, and how subordinate groups then are “often unable to convert their demands for change into important political issues” that are ever considered by policymakers (p. 105). Henry Kariel saw classic studies of American pluralism as elevating one particular institutional system, American pluralism, as both “irreducible, beyond analysis and critique” and objectively good, preventing systematic analysis of American institutions (p. 136).

Finally, Dianne M. Pinderhughes’s critical study of Chicago politics, *Race and Ethnicity in Chicago Politics: A Reexamination of Pluralist Theory* (1987), provided rich historical data on labor and housing markets, political participation, education, and the criminal justice system for black, Polish, and Italian immigrants, all of whom came to the city at roughly the same time and for similar reasons but had strikingly different patterns of social and political integration some decades on. Her work demonstrated that pluralist assumptions of black integration into American life based on the evolution of specific issue sets did not occur because of the substantial discrimination inherent in American political institutions and because black citizens’ own political attitudes led to a rejection of conventional American institutions and authority symbols. The assumptions about bargaining that undergird pluralist theories of issue-oriented politics cannot occur when the issues are not bargainable and the parties to the bargain are not equal.

**CONTEMPORARY PLURALISM**

Pluralism in political thought underwent something of a revival in the last two decades of the twentieth century. Building on the body of work such as that of Pinderhughes, pluralists have put the concept to use in defense of multiculturalism and diversity that run counter
to assimilationist nation-building projects. Pluralists have charged that modern majoritarian democratic institutions and laws privilege dominant racial, ethnic, or cultural groups and should be thoroughly democratized by giving greater attention to inclusion of these plural identity groups. Unlike earlier forms of pluralism, the diversity of groups is not composed of voluntary associations or civil society groups in the strict sense. Neither are these issue-focused interest groups. Rather, “plural” identities in this conceptualization are communal groups, typically understood to include ethnic, racial, religious, or cultural characteristics and based on identities that, while situational and fluid, are not easily acquired or discarded.

The roots of this strain of pluralist theory are to be found in part in the writings of social anthropologists and historians of the colonized world in the first half of the twentieth century. Studies of colonial empires in South Asia and Africa in particular led to a focus on “traditional societies,” which were plural in the sense of being composed of ethnic groups who retained strong attachments to their distinct religions, culture, languages, and community life and were held together by pressure and even force from the colonial power and, in the postcolonial period, by the newly independent state. These distinct social segments, living side by side but rarely interacting, led to the types of heterogeneous societies found in newly independent states. Theorists typically argued that the state was captured by one minority segment within the plural society. Kuper summarized these as societies “characterized by cultural diversity, social cleavage and dissensus” (Kuper and Smith 1969, p. 12). While the focus was often empirical and descriptive, the normative tone suggested ways to reduce the plurality, which was presumed to cause political and social conflict through assimilationist nation-building policies.

Subsequent studies in comparative pluralism have widened this contemporary understanding of pluralism by emphasizing that nearly all states in the modern world are heterogeneous and plural in the sense that M. G. Smith and Leo Kuper had argued colonial societies were. Pierre L. Van den Berghe suggested that pluralism can encompass not only subcultural ethnic and communal identities but also differences based on race, caste, and class. This signaled a transition in two somewhat distinct but conceptually related subfields of social and political inquiry: race and ethnic stratification in the Western democracies, and the various ethnic (and sometimes racial) cleavages found in the former colonies of the Middle East, Africa, Asia, and Latin America.

A flourishing interest in the empirics and theory of racial and ethnic differences in North America and western Europe has produced many strands of thought on pluralism, most with a focus on group-based citizenship. Scholars argued that the notion of a homogeneous Western nation-state was more a fiction than a reality. Michael Omi and Howard Winant’s concept of racial formation described the historical creation, deployment, transformation, and destruction of racial categories. Critical race theorists pointed to the distinct role that racial identities play in the context of a “racial state” and the social, political, and economic significance of group-based identities on life prospects for members. Philosophers such as Linda Martin Alcoff (2006) defended the attachment to cultural identities as ontologically real and fully defensible within a tradition concerned with individual autonomy and rationality. Political theorists asserted that political struggles over cultural diversity are at least as important in the West as elsewhere, and that only through “multicultural citizenship” (as Will Kymlicka put it in 1995) or “differentiated citizenship” (in Iris Marion Young’s 1991 formulation) can democracy or a just constitutional order be achieved. Critics of this approach, such as Brian Barry (2001), do not argue that there is a plurality of identity groups, but they insist that there is only one status of citizenship in a liberal democracy. Rights are, and should be, assigned to individuals as such, rather than to particular groups.

Paralleling this shift in Western thought on pluralism, and reflecting greater attention not just on a plurality of groups but specific kinds of groups (racial, ethnic, religious), was a deepening of theoretical attention to the nature of communal diversity in non-Western contexts. These theorists challenged perspectives like that of Kuper and Smith, which had focused on the conflict-prone nature of groups and seemed to point toward assimilationist nation-building projects. Donald L. Horowitz’s seminal study Ethnic Groups in Conflict (1985) attempted to explain not only the material and political basis of ethnic identities but also the psychosocial importance of relative group worth in plural societies. A wealth of literature has developed on the topic, much of it focusing on institutional engineering and conflict management in ethnically diverse societies (Lijphart), as well theoretical approaches accounting for the diverse citizenship models that emerge in the context of this kind of diversity (Berman, Eyoh, and Kymlicka).

What is increasingly clear is that various forms of pluralism, however constituted, are critical to the deepening of democracy. Pluralism disperses power and contributes to the vitality of the democratic community by acting as a check on a strong state. Further, it can support identification with the democratic state by recognizing and valuing the diverse communities to which citizens belong.

Plurality

As a mechanism for deciding political contests, elections held under plurality rules have the great apparent advantage of simplicity. Plurality elections are most commonly used to elect one candidate for one position. When the number of positions to be filled is one, the candidate with more votes than any other candidate is declared the winner. In some plurality elections, however, the number of positions to be filled is more than one—for example, four. In such elections, the positions are filled by the four candidates who win more votes than the other candidates.

But plurality elections are not as simple as they seem. Candidates are elected under plurality rules with more votes than the losing candidate or candidates. But when there are many more candidates standing for election than positions to be filled, successful candidates may receive far less than half the votes: For example, in an election in a single-member district for which there are 100 voters and five candidates, the winner might receive only 21 votes, three losers 20 votes, and the other 19. Sometimes the difference in number of votes between the winning and losing candidate in a single-member plurality election is called the majority. But more accurately, a majority is 50 percent plus one of all votes cast. In this case, in the election example above, the winner would receive 51 votes and the losing candidates 49 votes between them. Therefore, candidates elected under plurality systems where many more stand than can be elected do not necessarily have majority support.

Electoral theory posits that the number of candidates likely to be competitive in a plurality election is the number that can be elected plus one: where the position is for a single member, therefore, this equals two (Cox 1997), but this does not always happen. This claim is often extrapolated from a single election in one district to a general election across an entire country where parties compete. Thus plurality electoral systems are said to generate two-party systems, and, in particular, they tend to increase the number of successful candidates for the winning party.
beyond its share of the votes cast nationally. Plurality elections, in this context, are said to produce manufactured majorities among the persons elected. In this sense, plurality elections produce majority outcomes, and are thus often labelled majoritarian. Certain theories of democracy value this aspect of plurality elections because the consequent two-party systems are said to make possible alternation of office between moderate parties and enhance the stability, decisiveness, and accountability of governments.

However, this strength of plurality elections is most apparent where societies have one major social division and related political preferences are distributed across electoral districts in a way that can generate balanced two-party competition. Plurality elections worked successfully in many democratic societies during the twentieth century under these conditions. But if social divisions and preferences are distributed similarly in all districts, one party can in theory win all seats. And if there is more than one social division and associated sets of preferences are separated spatially among districts, a multiparty system will emerge (Kim and Ohn 1992). In essence, plurality elections privilege social divisions that are distributed spatially, but provide poor representation of those that are not. Given this, it remains debatable whether plurality can operate as a system of election in the increasingly socially heterogeneous societies of the twenty-first century as successfully as it did in the past.

POGROMS

The term pogrom is derived from the Russian pogromit (to create a desert) and describes forcible excursions and plunder against a specific ethnic or religious minority. Outbreaks of this kind occasionally occur spontaneously but are initiated by local or national forces. It is common for a significant portion of the majority population to take part in these persecutions; as a rule the authorities do not intervene to halt the violence.

The term is used in the twenty-first century to designate a variety of events, such as the persecution of the Armenians by Sultan Abdulhamid II (1842–1918) in the Ottoman Empire from 1894 to 1896; the attacks on Greeks in Istanbul, Turkey, in 1955; the murder of ethnic Chinese in Indonesia after the fall of President Ahmed Sukarno (1901–1970) in 1965; the harrying of the Ibo people in northern Nigeria in 1967; the agitation against the Sikhs in India following the assassination of Prime Minister Indira Gandhi (1917–1984); and the excesses against the Armenians in Baku, Azerbaijan, in 1990. The word gradually became part of the international vocabulary toward the end of the nineteenth century. Originally it meant only the anti-Semitic excesses of czarist Russia. Hence consideration of the pogroms directed against Jews in central and eastern Europe is key to the following discussion, along with consideration of their political and socioeconomic context and background.

EUROPEAN POGROMS: FROM THE MIDDLE AGES TO THE EARLY MODERN ERA

During the first two Crusades (1096–1102 and 1147–1149), the Jews of central Europe, especially in Germany, fell victim to persecutions and sacrifices. The initial nature of the conflict was religious. The persecutors justified their action with the argument that the liberation of the Holy Land should be preceded by the murder of the “murderers of Christ” in Europe. The actual motives of the perpetrators were more economic, however. The burgeoning religious fanaticism of the time presented a suitably legitimate opportunity to get rid of some economic competitors, because many Jews were involved in credit trades at the time. Yet it would be a mistake to equate the history of the Jews in medieval Europe with persecution and discrimination. There were certainly longer periods of relatively peaceful coexistence with the Christian world. Nonetheless, relations between Christians and Jews were precarious. Famines and epidemics inflamed the Christian majority against religious and social minorities. Thus the great epidemic and plague of the late Middle Ages in the mid-fourteenth century resulted in pogroms against the Jewish population. The Jews were accused of causing the plague by poisoning wells and streams. Hence the initial motive for the persecution was an attempt to explain the sudden appearance of the rapidly spreading illness. At the same time the hatred of the Jews this stirred up played into the hands of Christian debtors and merchants.

Mobilization against the Jews was further spurred by accusations of ritual murder. These assertions claimed that Jews stole Christian children and slaughtered them in order to use their blood for ritual purposes. This accusation, among others, served as a reason for the destruction
and plunder of the Prague Ghetto in 1389, which at the time contained the largest and wealthiest Jewish population in Europe.

Because the threat of persecution and expulsion constantly hung over their heads, beginning in the thirteenth century large segments of the Jewish population moved farther to the east. The Polish kings encouraged the settlement of Jews and guaranteed their security and economic privileges. The Jews soon became indispensable for the Polish economy, mediating as traders and brokers between town and country. The Polish nobility came to prefer leaving the administration of their property to Jews, which dragged the latter into conflicts between nobility and peasantry. In 1648 these tensions finally resulted in a pogrom of hitherto unseen magnitude, when Ukrainian peasants joined with Cossacks. Russian cavalry, led by Hetman Bogdan Chmelnytsky (1595–1657) and attacked Polish cities. As many as 125,000 Jews fell victim during these massacres. As a rule the Jews could not count on the support of their Polish neighbors, and it took decades for the Jewish communities to rebuild. One reaction to the catastrophe was the rising popularity of cabalistic doctrine among eastern European Jews and the spread of messianic apocalyptic sects. The eventual outcome of these movements was Hassidism, one of the most significant mystical-religious movements in Judaism.

POGROMS IN RUSSIA UNDER THE CZARS AND DURING THE REVOLUTION

A rise in anti-Semitism in Russia coincided with the shaking off of Mongolian rule and the strengthening of the Orthodox Church in the late Middle Ages. Czar Ivan IV (1530–1584) forced religious conversion on the Jews in the newly conquered territories and severely restricted Jewish trade. By the middle of the seventeenth century, Russia had become a great power in the region and annexed Poland in 1772, lending the “Jewish question,” that is, the question of how to deal with the unpleasant minority, a new urgency. Under pressure from Russian merchants fearful of Jewish competition, Catherine II (1729–1796), who ruled Russia from 1762 to 1796, issued a decree forbidding Jews from living in the Russian interior. Their territory was restricted to the so-called Pale of Settlement—the former territory of Poland and the area north of the Black Sea.

The nineteenth century saw a profound socioeconomic transformation of Russian society that also affected the life and economic activity of Jewish communities. The Jewish population concentrated itself in the cities inside the Pale of Settlement, focusing on trade; skilled trades and the cultivation of the land had become less profitable and therefore lost their appeal for most Jews. Although a small portion of the population established itself in banking and credit, most Jews became impoverished. From this point on Jews attempted to succeed as petty merchants, peddlers, and handicraftspeople. They thus found themselves in bitter, destructive competition with their Christian neighbors, which led to a rise in anti-Semitism. The Russian upper classes and nobility also became increasingly anti-Semitic, associating the Jews with modernization and capitalism (i.e., with movements that threatened the traditional social order). Thus anti-Semitism came to be associated with anticapitalism and antisocialism.

The hostility toward Jews was widespread in the Russian Empire: between 1881 and 1921 there were three devastating waves of pogroms. The first followed the assassination of Czar Alexander II (1818–1881), when anti-Semitic circles blamed his death on the Jews. The rumor spread like wildfire and gave an anti-Semitic mob justification for attacks on the Jewish community. Pogroms regularly ensued until 1884, primarily in southeastern Ukraine, but also in White Russia (later Belarus) and Lithuania. The Ukrainian pogroms were perpetrated primarily by migrant workers and railway employees. The local population, especially in the Ukraine, passively observed the plunder and violence and left the mobs unhindered, seeing these pogroms against an unloved minority as a suitable release for the pressures of unresolved social issues. Czar Alexander III (1845–1894) blamed the pogroms on the Jews themselves and drafted a series of discriminatory edicts against them in order to unite a divided population behind him. In their struggle for legitimacy, the Russian upper classes fanned the flames of already widespread anti-Semitism, misusing it as an ideology of social integration.

The outbreak of the second wave of pogroms, from 1903 to 1906, was linked directly to political developments in the czarist empire. In order to try to contain growing revolutionary sentiment, the government fanned anti-Semitism by inciting the conservative press against the Jewish population. The first pogrom of this era took place at the Jewish holiday of Passover in 1903 in the town of Kishinev, with roughly 1,500 Jewish houses and businesses looted. These pogroms were organized by the so-called Black Hundreds, an association of reactionary monarchist groups. The government instructed local authorities not to proceed against the perpetrators. Representatives of the czarist secret police wrote and disseminated anti-Semitic pamphlets, such as the infamous Protocols of the Elders of Zion, which blamed the Jews for all the country’s ills. After the Reform Edicts of 1905, which extended suffrage to the Jews and established the Duma (i.e., the Russian parliament), the most devastating pogrom to date occurred involving sixty-four cities and six
hundred villages. More than eight hundred Jews fell victim to its violence.

The wave of pogroms from 1917 to 1921 occurred in the context of world war, revolution, and civil war. Even before the end of World War I (1914–1918), deserters committed terrible massacres and robberies of Jewish property in villages near the front. After the Bolshevik October Revolution in 1917, units of the Red Army and more particularly counterrevolutionary forces (the so-called White Russian, anti-Bolshevik armies) fell on the Jewish population in towns and cities. The worst pogroms took place in the Ukrainian Republic. Before the pro-Bolshevik Red Army's victory in 1920, over sixty thousand Jews lost their lives in the violence.

As a result of the constant pogroms and growing legal and social discrimination, from the 1880s onward many young Jews joined the socialist opposition. A Jewish national consciousness also developed, culminating in Zionism. The Zionists believed that Jewish integration into eastern European society had failed and that the sole solution to the "Jewish question" was the creation of a Jewish national state. During this time also Jewish emigration to the United States (and also to Palestine) rose steadily.

POGROMS IN GERMANY
German Jews only achieved full civil rights with the creation of the Second German Empire, following the French defeat in the Franco-Prussian War in 1871. But the path was a bumpy one. In 1819 some manual workers, merchants, and students took the discussions initiated by Jewish emancipation as an occasion for pogroms in several German cities. During the nineteenth century a large portion of the Jewish population in Germany was able to achieve some social progress; however, by the 1870s several anti-Semitic parties had formed with the explicit aim of reversing the social equality and integration of the Jews. After the beginning of the twentieth century, most of these parties sank into insignificance. Although anti-Semitism was as widespread and significant a political force in Germany as in surrounding European states, it was considerably less powerful than in eastern European states.

Extreme nationalism during World War I had already led to a growing climate of anti-Semitism. After the end of the war, nationalist and populist groups, such as the right-wing extremist party the National Socialist German Workers’ Party (NSDAP), blamed German Jewry for the defeat as well as the succeeding economic misery. For many members of the NSDAP Judaism and bolshevism (anticapitalism) were synonymous; both phenomena were treated as dangerous to traditional social and political order.

The systematic disenfranchisement and exclusion of German Jews began soon after the NSDAP’s seizure of power in January 1933. The first pogrom against the Jews during this period broke out on 9 and 10 November 1938 and was referred to as Reichskristallnacht or Kristallnacht (night of broken glass). But this incident was anything but a spontaneous expression of violence. Members of the NSDAP and the Gestapo (the secret security police of the NSDAP) as well as paramilitary organizations such as the Sturmabteilung (SA) started fires in synagogues across Germany and plundered Jewish businesses. In the process they murdered one hundred German Jews. The German police had received orders that under no circumstances were they to intervene on behalf of the Jews. A small portion of the population participated in the pogrom, especially the plunder, while most Germans observed the events passively without participating. The NSDAP government had attempted to portray the pogrom as a spontaneous reaction by the Germans to the assassination of a German diplomat by a Jewish conspirator in Paris. The NSDAP government had three goals in the November pogrom. Initially forces within the party for whom existing anti-Jewish measures were insufficiently radical were to be mollified. Moreover the Nazi leadership sought to further intimidate the Jews and encourage their emigration. Finally, the pogrom accelerated the systematic persecution and dispossession of the Jews, a process referred to as “aryanization.”

During World War II members of the NSDAP, or Nazi Party, committed countless pogroms against Jewish populations in occupied areas of eastern Europe. The local populations generally cooperated willingly with the occupiers and permitted themselves to be dragged into deeds of violence against their Jewish neighbors. On occasion, such as in the Polish town of Jedwabne, the local population did not wait for the arrival of the German conquerors and murdered the Jewish population on their own initiative. The prospect of taking over Jewish property was every bit as much to blame for this turn of events as historically deep-rooted anti-Semitism.

The czarist pogroms in Russia and the November 1938 pogrom in Germany all occurred with government participation in the planning and the violence. Nonetheless, the involvement of the population in Russia was considerably greater than in Germany, since the integration of Jews into German society was considerably more advanced than in Russia. Thus the aim of the 1938 pogrom was not so much to push social and political problems into the background and unite a politically and socially divided populace.

POL POT

1925?–1998

Pol Pot was the ruler of Cambodia from 1975 to 1979 and presided over one of the worst genocides of the twentieth century. In approximately 1925 (the exact date of this birth remains unclear), he was born Saloth Sar to a fairly well-to-do family in Kompong Thom Province, Cambodia. Although Pol Pot's political zest developed while he was in his home country, his path to political leadership began to be forged after his arrival in Paris in 1949 to study radio electronics. There he became a member of the French Communist Party and met other Cambodian intellectual elites who would become powerful figures in the years 1975 to 1979.

Having failed his exams three years in a row, Pol Pot (a nom de guerre, short for the French *politiq ue potentielle*) returned to Cambodia in January 1953. He had, however, become well-versed in socialism and communism—his intellectual models were Vladimir Ilyich Lenin, Leon Trotsky, Joseph Stalin, and Mao Tse-tung—and his opposition to the government of Prince Norodom Sihanouk led him to join the Communist resistance. Pol Pot became a member of the Indochina Communist Party, which was dominated by Viet Minh, within a month after his return. He then joined the Cambodian Communist Party Group, whom Sihanouk named the Khmer Rouge or Red Cambodians, and became secretary general in 1962. This group then started agitating against the Phnom Penh government. Ultimately, through armed rebellion, the Khmer Rouge gained full control of the country. The party took power on April 17, 1975, less than two weeks before the fall of Saigon ended the Vietnam War, and renamed the country Democratic Kampuchea. One of the Khmer Rouge's first acts was to implement a complete evacuation of Phnom Penh to the countryside.

Under his four-year plan, Pol Pot's stated aim was to turn Cambodia into a Maoist agrarian utopia; he planned to nationalize all industry and finance the economy through increased agricultural exports. His regime seized all legislative and judicial powers. Every Cambodian was forced to become an unpaid agrarian laborer and was allowed limited food and rest. Under the four-year plan, at least one million Cambodians died as a result of starvation, disease, or murder. Anyone suspected of betraying the government was killed.

Throughout the late 1970s relations with Vietnam worsened. Pol Pol's government was toppled on January 7, 1979, by the invading Vietnamese army. Pol Pot himself never surrendered; he fled into the jungle near Thailand and led a Khmer Rouge guerrilla war from there. As Cambodia worked to return to normalcy, it remained under threat from the Khmer Rouge, which never recognized the Phnom Penh government and claimed some western provinces on the border with Thailand. Pol Pot maintained his opposition to the new coalition government until the national elections of 1993. Never brought to justice for having decimated his country, he died on April 15, 1998, in the Thai-Cambodian border area.

POLICING, BIASED

Biased policing refers to the practice of law enforcement officers or agencies of systematically targeting certain groups in society for suspicious activities. Instead of being judged as innocent until proven guilty, targeted groups tend to be considered guilty first and questioned about their innocence later. Police biasing often takes the form of racial and ethnic profiling. However, biased policing may also be directed at gay men and lesbians, people who
occupy the lower-class rungs of society, or groups that do not exemplify the normative behaviors expected in society (e.g., biker gangs, religious cults). In the past, research on biased policing was typically centered on local and state law enforcement agencies, such as city and state police and sheriff’s departments. However, since about the mid-1990s there has been increasing research on federal law enforcement agencies that engage in biased policing (e.g., the Federal Bureau of Investigation, the Department of Homeland Security).

Biased policing is a form of institutional and systemic racism. Using Eduardo Bonilla-Silva’s (2006) notion of the “racialized social system,” biased policing can be seen as one form of social control against groups who are considered “outsiders.” As such, biased policing helps to maintain the white middle-class structure that dominates U.S. society. This form of negative profiling has existed in American society since the slavery era, when “black codes” were institutionalized to regulate both free and enslaved blacks (Jordon 1968; Marable 2000). Both groups were heavily monitored by slave patrols, whose duties included not only punishing runaway slaves but also free blacks who were considered threatening to whites. These slave patrols were usually organized groups of three to six white men who patrolled plantations, state borders, and state roads, profiling people who did not fit the skin color and phenotype of white Europeans.

Although most law enforcement agencies have policies that clearly state that any form of biased policing, including racial profiling, is deemed unacceptable, the American Civil Liberties Union maintains that tens of thousands of Americans face some sort of biased policing everyday. Furthermore after the September 11, 2001, terrorist attacks on the World Trade Center in New York City and the Pentagon in Virginia, biased policing and, more specifically, racial profiling reached a new high in regard to the number of people who are affected by these extreme forms of social control.

The form that biased policing takes varies depending on the law enforcement agencies involved, the personal characteristics of the law enforcement officers, whether state or federal laws are involved, and the location. For example, after the passage in 2001 of the Patriot Act, designed to expand the authority of U.S. law enforcement agencies for the purpose of fighting the threat of terrorism in the United States, an increase in racial profiling against Arab and Muslim Americans took place and was justified under the guise of fear (Muneer 2002). Forms of biased policing include the stopping of motorists, the detention of a person or group of people, or the searching of a person’s vehicle, home, or body based on any number of characteristics, including race, ethnicity, gender, age, or income status. Common forms of biased policing include harassment of specific groups of people at malls, workplaces, and even political gatherings. For example, numerous blacks reported being harassed by local police on their way to voting booths during the 2000 presidential election in Florida. In addition a large number of Latinos report harassment by law enforcement officers on their way to work, school, or home as a result of controversies concerning immigration in the United States.

RACIAL PROFILING

Of the various forms of biased policing, the most notable and well researched concerns discrimination by race or ethnicity. This type of biased policing is known as racial profiling and refers to the systematic targeting of a person or group based solely on race or ethnicity. In other words, other than a person’s race or ethnicity, there is no reasonable justification for stopping or detaining him or her. The issue of racial profiling has been such a frequent problem for blacks and Latinos in the United States that new slang terms have been created to describe such instances (Lundman and Kaufman 2003). For example, the stopping and searching of blacks and Latinos for “suspected” traffic violations is commonly referred to as DWB (i.e., driving while black) or DWM (i.e., driving while Mexican).

After the 2001 terrorist attacks, U.S. law enforcement agencies slightly shifted their focus on blacks and Latinos to include Arabs and Muslim Americans and even South Asian Americans as racially profiled targets. The matter has become increasingly complex as poll data indicate that a majority of blacks and Latinos may support racial profiling against Arab and Muslim Americans.

COUNTERARGUMENTS

Although numerous studies indicate that biased policing and racial profiling continue to be a major issue in the United States, a number of studies argue that the issue of racial profiling has been overstated or that such practices are necessary given the terrorist threat. For instance, Michael Smith and Matthew Petrocelli (2001) argued that while black drivers were pulled over more frequently than white drivers, there was no data that suggested that vehicles driven by blacks were more frequently searched. Moreover, controlling for certain variables, blacks were more likely to be issued a warning, whereas white drivers were more likely to be ticketed or arrested. In addition to research that favors biased policing, numerous articles in the mainstream press argue that racial profiling does not occur. For example, Heather MacDonald (2003) reported in the Los Angeles Times that police officers who were labeled as racist were in fact just doing their jobs. MacDonald further argued that what appeared to be racial profiling was really just “good policing.” However, the
problem with the majority of such studies and articles resides in their limited sampling techniques; as such, they do not reflect the overwhelming data that find that biased policing and racial profiling continue to be major issues in the United States.

POLICY, FISCAL
Fiscal policy is the use of a government’s spending, taxing, and debt issuance authority for the purpose of influencing economic activity. The origins of fiscal policy are rooted in the worldwide economic depression of the early twentieth century (1929–1939). Prior to that time, there was little in economic theory or practice suggesting the deliberate use of the government’s authority to achieve particular economic ends. Rather, emphasis was placed on the government’s role in creating a favorable environment for private economic activity.

DYNAMIC PRINCIPLES
A tool for understanding fiscal policy is government’s intertemporal budget constraint. This constraint relates the path of government spending to the path of government receipts. It highlights the fact that a government’s budget need not be balanced each time period. However, the present value of current and future government spending must equal the present value of government revenue.

To fix the ideas, let $G$ equal current government spending, $G^f$ equal future government spending, $T$ equal current taxes imposed on the private sector, $T^f$ equal future taxes imposed on the private sector, and $r$ equal the real rate of interest. Further, let $D$ equal the government’s current budget deficit. That is, $D = G - T$. The government finances the deficit by selling an equal amount of government bonds.

In the future, the government must collect enough taxes to repay the debt (including interest) and to pay for future government purchases. That is, $T^f = (1 + r)(D + G^f)$. Substituting into this latter equation the expression for $D$ and rearranging yields a government’s intertemporal budget constraint:

$$G + G^f / (1 + r) = T + T^f / (1 + r)$$

The left-hand-side of this expression is the present value of government purchases. The right hand side is the present value of government taxes. A fundamental fiscal policy lesson learned from this analysis is that all government spending ultimately must be reconciled with current and/or future government taxes so that the government’s intertemporal budget constraint is satisfied.

Recognition of the government’s budget constraint is crucial for assessing the impact of fiscal policy on long run economic growth. Neoclassical growth theory suggests that fiscal policy’s only impact is on the level of output per capita and the transition dynamics from one per capita output level to another. On the other hand, endogenous growth models suggest that fiscal policy can affect the steady state rate of economic growth. Key to this prediction is the distinction between distortionary and non-distortionary taxation and productive and nonproductive expenditures. Using data from twenty-two Organisation for Economic Co-operation and Development (OECD) member countries, in 1999 Richard Kneller, Michael Bleaney, and Norman Gemmell demonstrated that if appropriate account is taken of the implicit financing of government spending, then the evidence suggests that distortionary taxation (income, profit, property, and payroll taxes) reduces growth and productive government expenditure (education, health, housing, and transportation spending) enhances growth.
STABILIZATION CAPACITIES
Because the government is not constrained to balance its budget period-by-period, it may adopt other objectives for its spending and taxing authority in the short run. One short-run objective that has been adopted is stabilization of the macroeconomy. Discretionary fiscal policy seeks to moderate fluctuations in overall economic activity by adjusting government expenditure or taxes. (Whether there is much scope for effective discretionary fiscal policy is controversial.) Traditional macroeconomic theory suggests that for a closed economy performing below its potential, an increase in government expenditure will stimulate aggregate expenditure. Private business firms respond to the increase in expenditure by raising production and employment. The total rise in production exceeds the increase in government spending because of a chain reaction of private consumption spending induced by the initial government expenditure. This chain reaction of spending is called the multiplier. An alternative, though slightly less potent, way for the government to trigger a chain reaction of spending is to reduce the amount of taxes it collects from the private sector. These policies also work in reverse. Therefore, if the economy is performing above its potential, the government can reduce its expenditures or raise taxes to prevent the economy from overheating.

Empirical evidence from the United States in the post–World War II period suggests that shocks to government spending and taxes effect real gross domestic product (GDP) in a manner that is broadly consistent with the aforementioned description. According to a 2002 study by Olivier Blanchard and Roberto Perotti, increases in government spending raise real GDP contemporaneously and over time. The peak dynamic effect of the increased spending on GDP occurs between one and fifteen quarters in the future. Tax increases, on the other hand, lower real GDP contemporaneously and over time. The peak dynamic effect of tax increases on GDP occurs between five and seven quarters in the future.

In order to detect the impact of discretionary fiscal policy, it is necessary to account for important yet passive changes in spending and taxation by a government. Automatic stabilizers are changes in spending and taxation that occur in response to changes in economic activity. They do not require initiative by a government. Transfer payments such as unemployment insurance and tax payments linked to income are examples of automatic stabilizers. Net tax payments (taxes minus transfers) tend to rise during economic expansions and fall in recessions.

OPEN ECONOMY CONSIDERATIONS
The effectiveness of fiscal policy in economies open to international trade depends on several factors, including whether a country is large or small relative to the size of the world economy, whether capital can flow freely in and out of the country, and whether a country’s exchange rate is fixed or floating.

Consider, for example, the case of a small country with capital mobility and a flexible exchange rate. Such a country takes the world interest rate as given. Further, the domestic interest rate equals the world interest rate plus a risk premium. An increase in government expenditure increases aggregate spending. The rise in spending will cause an incipient rise in the domestic interest rate. Capital from abroad will be attracted to the domestic country causing the country’s exchange rate to appreciate. Net exports will fall in response to the appreciation, thereby choking off the expansion of domestic production. In the end, there will be no expansion of total output. Fiscal policy’s only impact will be to change the composition of the initial level of output. The government sector is larger. The export sector is smaller. The theoretical prediction that fiscal policy is totally ineffective in this case stands in stark contrast to the closed economy case previously discussed.

Canada is a relatively small country whose characteristics closely match those described. The evidence from Canada suggests that the impact of fiscal policy on economic activity at the business cycle frequency is small at best. In 2005 Perotti estimated that the cumulative response of real GDP to positive shocks to government spending is positive but less than one, suggesting that there is no multiplier effect. In fact, in the post-1980 period, the cumulative response of real GDP to positive shocks to government spending is actually estimated to be negative. Tax cuts are estimated to stimulate economic activity in Canada. This finding, however, appears to be particular to Canada as it was not the case in any of the other OECD countries studied by Perotti.

DIFFICULTIES WITH FISCAL POLICY
Several issues make the theory and practice of fiscal policy controversial and difficult. First, there is uncertainty as to how fiscal policy should be measured. A generational accounting approach, such as the one taken by Laurence Kotlikoff, would focus on the lifetime tax burden born by different age cohorts. Second, lags in the recognition of the need for a policy change, the design of a new policy, and the implementation of a new policy may render fiscal policy too ponderous to be timely. Third, private sector expectations may thwart fiscal policy. According to a 2003 article published by Alan Auerbach in Brookings Papers on Economic Activity, tax changes known to be temporary, for example, are likely to have different affects than those that are permanent. Finally, fiscal policy makers may not be
able to resist the temptation to renege on tax and spending promises in order to realize short-term gains. According to Edward Prescott's 2004 work, this time inconsistency problem may cause more damage to the economy in the long run because the private sector may lose confidence in the government.

SEE Foreign Policy.

POLICY, MONETARY
Monetary policy is the management of money, credit, and interest rates by a country's central bank. Unfortunately, this short definition is clearly inadequate. What is money? What is credit? What is an interest rate? And, most importantly, why should anyone care? The purpose of this entry is to answer these questions (for more detail, see the relevant chapters of Stephen G. Cecchetti [2006]).

A FEW BASICS
Money is an asset that is generally accepted as payment for goods and services or repayment of debt; money acts as a unit of account, and serves as a store of value. That is, people use money to pay for things (it is a means of payment); quote prices in dollars, euros, yen, or the units of our currency (it is a unit of account); and use money to move purchasing power over time (it is a store of value). Credit is the borrowing and lending of resources. Some people have more resources than they currently need (they are savers) while others have profitable opportunities that they cannot fund (they are investors). Credit flows from the savers to the investors. And an interest rate is the cost of borrowing and the reward for lending. Since lenders could have done something else with their resources, they require compensation—interest is rent paid by borrowers.

THE CENTRAL BANK
The U.S. Federal Reserve System, the Bank of Japan, and the Bank of England are all central banks. Nearly every country in the world has a central bank. It is easiest to understand a central bank by looking at what it does (for a history of money and central banks, see Glyn Davies [2002]). A modern central bank both provides an array of services to commercial banks (it is the bankers' bank) and manages the government’s finances (it is the government's bank). While not universally true, we will assume that only banks and governments have accounts at central banks. As the bank for bankers, the central bank holds deposit accounts and operates a system for interbank payments that enables commercial banks (the ones the public uses) to transfer balances in these accounts to one another. The central bank is also in a unique position to provide loans to commercial banks during times of crisis—more on this shortly.

Like any individual or business, the government needs a bank to make and receive payments. So, the central bank keeps an account for the government. When the government wants to make or receive a payment, it needs a bank just like the rest of us. The central bank does that job. In addition, the government gives the central bank the right to print money—that is the paper currency that people use in everyday life.

At its most basic level, printing money is a very profitable business. A $100 bill costs only a few cents to print, but it can be exchanged for $100 worth of goods and services. It is logical then that national governments create a monopoly on printing money and use the revenue it generates to benefit the general public. Also, government officials know that losing control of the money printing presses means losing control of inflation.

CONTROLLING MONEY, CREDIT, AND INTEREST RATES
The fact that the central bank has the license to issue money makes it unique. If individuals want to make a purchase, they need to have the resources to do it. So, for example, someone using a debit card to purchase groceries

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 293
will have to have sufficient balances in a commercial bank account to cover it. If the grocery purchaser does not have sufficient resources of his own, he will need the financial assistance of someone who is willing to make him a loan. The central bank is different. If the central bank wants to buy something—say a government-issued bond—it can just create the liabilities to do it. Essentially it can issue the money. Importantly, the central bank can expand the size of its balance sheet at will. No one else can do this.

The central bank uses its ability to expand (and contract) its assets and liabilities to implement monetary policy. Figure 1 is a simple version of the central bank's balance sheet, stripped of a number of incidental items (like buildings and gold). When looking at any balance sheet, the most important thing to remember is that assets equal liabilities, so any change in one side must be matched by a change in the other. When a central bank purchases a government security, increasing its assets, this is normally matched by an increase in commercial bank reserve liabilities. Banks hold these reserves both because they are required by law and in order to make interbank payments.

At its technical, day-to-day level, monetary policy is all about buying and selling securities to control the quantity of reserves in the commercial banking system. Modern central banks, like the Federal Reserve or the European Central Bank, use their monopoly over the supply of commercial bank reserves to control an interest rate of their choosing. In some, like the Reserve Bank of Australia, it is the deposit rate the central bank pays commercial banks on the balances in their reserve account. In the United States, it is the federal funds rate—the rate banks charge each other for overnight loans of reserves. The Federal Reserve decides on its target for the federal funds, and then buys and sells securities to set the supply of reserves to hit this target. Twenty-first century monetary policy is not about controlling the quantity of money or its growth rate; it is about interest rates. (For a technical discussion of the use and the abandonment of money as a target, see Laurence Meyer [2001a]. For a detailed discussion of the monetary policy of the European Central Bank, see Otmar Issing et al. [2001]).

It is important to note that some central banks decide to use their ability to control the size of their balance sheet to target something other than interest rates. The natural alternative is the exchange value of their currency—that is, the value of the number of dollars it takes to purchase the currency issued by another central bank. But, by the beginning of the twenty-first century, this had become increasingly rare. A central bank cannot control the total quantity of money and credit in the economy directly, and no modern central bank tries.

Finally, in addition to the size of their balance sheet, central banks have two additional tools. During times of financial stress, the central bank stands ready to provide loans to banks that are illiquid (so they cannot make payments) but still solvent (so their net worth is positive). Policymakers set interest rates on these loans. When the lending is done properly, this eliminates financial systemwide panics. In addition, central banks in many countries are given the power to set requirements governing how banks hold their assets. So, for example, they may require a certain level of reserve deposits, or prohibit the holding of common stock.

**MONETARY POLICY OBJECTIVES**

The central bank is part of the government. Whenever an agency of the government involves itself in the economy, people need to ask why. What makes individuals incapable of doing what they have entrusted to the government? In the case of national defense and pollution regulation, the reasons are obvious. Most people will not voluntarily contribute their resources to the army, nor will a country's citizens spontaneously clean up their own air.

The rationale for the existence of a central bank is equally clear. While economic and financial systems may be fairly stable most of the time, when left on their own they are prone to episodes of extreme volatility. In the absence of a central bank, economic systems tend to be extremely unstable. The historical record is filled with examples of failure, such as the Great Depression of the 1930s, when the American banking system collapsed and economic activity plummeted.

Central bankers adjust interest rates to reduce the volatility of the economic and financial systems by pursuing a number of objectives. The three most important are: (1) low and stable inflation; (2) high and stable real growth, together with high employment; and (3) stable financial markets. Let’s look at each of these in turn.

The rationale for keeping the economy inflation-free is straightforward. Standards, everyone agrees, should be standard. A pound should always weigh a pound, a mea-
suring cup should always hold a cup, a yardstick should always measure a yard, and one dollar should always have the same purchasing power. Maintaining price stability enhances money’s usefulness both as a unit of account and as a store of value.

Prices are central to everything that happens in a market-based economy. They provide the information individuals and firms need to ensure that resources are allocated to their best uses. When a seller can raise the price of a product, that is supposed to signal that demand has increased, so producing more is worthwhile. Inflation degrades the information content of prices, reducing the efficient operation of the economy.

Turning to growth, central bankers work to dampen the fluctuations of the business cycle. Booms are good; recessions are not. In recessions, people lose their jobs and businesses fail. Without a steady income, people struggle to make their auto, credit card, and mortgage payments. Consumers pull back, hurting businesses that rely on them to buy products. Reduced sales lead to more layoffs, and so on. The longer the downturn goes on, the worse it gets.

Finally, there is financial stability. The financial system is like plumbing: when it works, it is taken for granted, but when it does not work, watch out. If people lose faith in banks and financial markets, they will rush to low-risk alternatives, and the flow of resources from savers to borrowers will stop. Getting a car loan or a home mortgage becomes impossible, as does selling a bond to maintain or expand a business. When the financial system collapses, economic activity also collapses.

THE POLICY FRAMEWORK

Central banks use their ability to control their balance sheet to manipulate short-term interest rates in order to keep inflation low and stable, the growth high and stable, and the financial system stable. But what makes monetary policymakers successful? Today, there is a clear consensus that to succeed a central bank must be: (1) independent of political pressure; (2) accountable to the public; (3) transparent in its policy actions; and (4) clear in its communications with financial markets and the public.

Independence is the most important of these elements. Successful monetary policy requires a long time horizon. The impact of today’s decisions will not be felt for a while—not for several years, in most instances. Democratically elected politicians are not a patient bunch; their time horizon extends only to the next election. Politicians are encouraged to do everything they can for their constituents before the next election—including manipulating interest rates to bring short-term prosperity at the expense of long-term stability. The temptation to forsake long-term goals for short-term gains is simply impossible to resist. Given the ability to choose, politicians will keep interest rates too low, raising output and employment quickly (before the election), but resulting in inflation later (after the election).

Knowing these tendencies, governments have moved responsibility for monetary policy into a separate, largely apolitical, institution. To insulate policymakers from the daily pressures faced by politicians, governments must give central bankers control over their budgets, authority to make irreversible decisions, and long-term appointments.

There is a major problem with central bank independence: It is inconsistent with representative democracy. Politicians answer to the voters; by design, independent central bankers do not. How can people have faith in the financial system if there are no checks on what the central bankers are doing? The economy will not operate efficiently unless policymakers are trusted to do the right thing.

The solution to this problem is twofold. First, politicians establish the goals for the independent central bankers, and second, monetary policymakers publicly report their progress in achieving those goals. Explicit goals foster accountability and disclosure requirements create transparency. While central bankers are powerful, elected representatives tell them what to do and then monitor their progress.

The institutional means for assuring accountability and transparency differ from one country to the next. In some countries, such as the United Kingdom and Chile, the government establishes an explicit numerical target for inflation. In others, such as the United States, the central bank is asked to deliver price stability as one of a number of objectives (for a discussion of the structure of central bank objectives, see Laurence Meyer [2001b]).

THE FUTURE OF MONEY AND MONETARY POLICY

In the early 1980s, nearly two out of three of the countries in the world were experiencing inflation in excess of 10 percent per year. In the early twenty-first century, this is one in six. Two decades ago nearly one country in three was contracting. By 2005, five in six countries were growing at a rate in excess of 2 percent per year. But not only has inflation been lower and output higher, both inflation and output appear to be more stable. And careful empirical analysis shows that monetary policy is a likely source of this low, stable inflation and high, stable growth (see Cecchetti, Flores-Lagunes and Krause [2006]).

Central bankers’ success can be traced to their ability to control interest rates. And their ability to manipulate interest rates relies on their control of the size of their balance sheet. This, in turn, requires that banks and individuals actually demand central bank liabilities. That is, people have to want to hold the currency issued by central banks,
and commercial banks have to demand reserves. Won’t the day come when no one wants this stuff anymore? And when that happens, won’t monetary policy disappear?

The answer is almost surely no. While it is true that the creation of a secure and anonymous substitute for paper currency will ultimately cause dollar bills and euro notes to disappear, reserves are different. The central bank operates an interbank payments system based on reserves. It does this to ensure that, even during periods of crisis, banks can continue to make payments. And to ensure that commercial banks use their payments system, the central bank offers cheap access to this system—that is, it subsidizes the cost of the system’s operation. So long as banks want reserves, there will be monetary policy (for a discussion of the challenges facing monetary policy makers, see Gordon Sello and Chairmaine Buskas [1999] and Laurence Meyer [2001c]).

POLICY ANALYSIS

Policy analysis is the art and science of determining which public policy, from among alternatives, will most likely achieve a determined set of goals. The art of policy analysis involves putting together pieces to determine what will work in public policy. Central to policy analysis is an understanding of the evolutionary process of policy development as policymakers strive to improve the policymaking process in general and specific policies in particular. Policy analysis is the activity of generating knowledge both of and in the policymaking process. Creating such knowledge includes the examination of the causes, consequences, and performance of public policies and programs. Unless this knowledge is shared with decision makers and the relevant public, the process of policy analysis is unfinished.

Policy analysis is a relatively young field of study. Traditionally, institutions and the processes of public policymaking were the primary concern of social scientists and political scientists. In 1951 sociologist Daniel Lerner (1917–1980) and political scientist Harold Lasswell (1902–1978) introduced the concept of “the policy sciences.” Their work is often cited as the foundation for the evolution of how public policies are studied. Over time, the traditional approach expanded to include analysis of the content and process of actual policies, a discipline that is now commonly referred to as policy analysis.

Policy analysis, a part of the larger field of policy studies, evolved and developed in the 1960s and 1970s. Various stimuli have been cited as promoting the growth of the field. Social concerns over civil rights, women’s liberation, the Vietnam War (1957–1975), the politics of the Middle East, rising energy costs, inflation, and environmental protection were among the stimuli. The expanding relationship between government and the academic community, along with government’s increasing reliance on the assistance of the academic community for developing methods of maximizing output in the face of diminishing resources, also facilitated the expansion of the field. Additionally, government offered expanding research funding and job opportunities as it sought assistance in addressing the above-mentioned social issues. New analytical and interdisciplinary methods allowed academics and think tanks to capitalize on government expansion. The Keynesian revolution in economics (1930s and 1940s) is one such development. This revolution allowed for public sector intervention in the economic decision-making process. Applied policy research continues to play a major
role in contemporary government decision making around issues of efficiency, effectiveness, and equity.

Although heavily influenced by the disciplines of political science, policy analysis is eclectic as it borrows from and lends to a myriad of academic disciplines. Economics, for example, contributes cost-benefit analysis and models relating to the optimal allocation of resources. Policy analysis also incorporates the emphasis in economics on prescriptive conclusions. Psychology lends to policy analysis the research paradigm of experimental and control groups and various techniques of statistical inference. Additionally, psychology provides theories and insights on the application of rewards and punishment as tools for promoting specific behaviors. Sociology’s concern with social problems has also added to the development of the study of public policies. In addition, the comparative analysis of public policies has roots in anthropology, geography, and history.

Methods of policy analysis vary from analyst to analyst. Various schools of thought, such as behaviorist, post-behaviorist, and rational choice theory, among others, influence analysts in terms of what types of questions are asked and what methods are employed to answer these questions. Public policy analysts rely on a number of different approaches. Analysts can take an empirical approach, designed to primarily determine the causes and consequences of public policies. A central goal of such an approach is to understand a policy problem. Such an approach tends to yield more descriptive and predictive information. An analyst can also use an evaluative approach, where the central question concerns the value or worth of past or future policy prescription. Finally, analysts using a normative approach ask what should be done. Their work thus yields more prescriptive types of knowledge. Analysts can also study policy content or the policy process itself.

Over the years, different methodological tools and approaches have been employed in the analysis of public policy. Theories derived from management, organization development, and psychology, in conjunction with the use of economic and political models, influence the techniques used by policy analysts. Analysts draw from a bank of both qualitative and quantitative methods. These include, but are not limited to, case studies, economic modeling, quasi-experimental approaches, causal-path analysis, operations research, and correlations analysis.

**POLITICAL CONVENTIONS**

National political party conventions have been the scene of some of the most dramatic moments in U.S. electoral history and have often changed the course of that history. These weeklong gatherings, held in the summer months every four years, enable delegates of the major political parties to meet and officially nominate their candidates for the presidency and vice-presidency and adopt a statement of principles. Despite this rich history, various circumstances fostering a more egalitarian nominating process and the explosion of instantaneous modern media coverage of events have rendered modern national party conventions less relevant than those of the past.

**ORIGINS**

Early in the nation’s history, the congressional leaders of political parties met in party caucuses to select presidential candidates. These meetings were sometimes held in secret. In the 1824 presidential election, Andrew Jackson (1767–1845) won 43.9 percent of the popular vote, but because no candidate had received the requisite number of electoral votes to win the presidency, the election was thrown into the House of Representatives as directed by the

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 297
Constitution. Thanks to some adroit political dealing, John Quincy Adams (1767–1848), who had won just over 30 percent of the popular vote, was elected president. Supporters of Jackson decried King Caucus and accused Congress of ignoring the will of the people. Presidential nominating caucusing disappeared after the 1824 election in favor of national nominating conventions. The first such convention was held by a single-issue party, the Anti-Mason Party, at Baltimore, Maryland, in 1831. Other than being the first party to hold a national convention and running a candidate who won seven electoral votes in the election, the Anti-Mason Party faded from the scene after its significant historical contribution. The Democratic and Whig Parties held national conventions in 1832, and the Republican Party did so in 1854 after replacing the defunct Whigs as a national party.

Ideally national conventions were to be a transparently democratic nominating setting. This was hardly the case, however. Delegates to party conventions were almost always selected by and/or under the control of the party boss, or individual who had risen to power via enormous networks of support or through less-than-ethical methods. In the late nineteenth century, New York state politics were controlled by Senator Thomas Platt (1833–1910). His dislike of, and inability to control, New York governor Theodore Roosevelt (1858–1919) led Platt to demand enough delegates to the 1898 Republican Convention to nominate Governor Roosevelt for the vice-presidency, in effect removing him from office in New York. Although Roosevelt was eventually elected vice president and Platt and his colleagues congratulated themselves on their successful tactics, the plan backfired when President William McKinley (1843–1901) was assassinated, and Roosevelt became president of the United States in 1901.

Often, party conventions presented previously unknown individuals to head presidential tickets. These no-names resulted from deadlocked ballots and political dealing and intrigue behind closed doors. In 1844, the Democratic Convention nominated James K. Polk (1795–1849) after nine ballots. Polk was not even mentioned on the first seven of those ballots, but was seen as an acceptable compromise and, finally, the nominee. Polk won the general election. Similarly Franklin Pierce (1804–1869) was not even a candidate entering the 1852 Democratic Convention, but became the nominee and won the presidency. Intrigue became absurdity when, during the 1924 Democratic Convention, John W. Davis (1873–1955) emerged as the nominee after 103 ballots, a drama that was closely followed by Americans across the land via a new technological development called the radio.

One traditional function of national party conventions is the debate over, and eventual adoption of, a party platform. The platform is a statement of party principles and the purported foundation upon which the party’s candidates will conduct their campaigns, and upon which the party stands for the subsequent four years. The proposals approved by the delegates and the stated goals are called planks. Platforms are now often ignored both by the candidates and the public at large, though they were much more useful in outlining a party’s views for the public before the evolution of mass media. Platform committees construct a platform document for delegate approval. At times, planks relating to difficult issues such as abortion have divided delegates, but not enough to make a significant mark during a convention. More often than not, platform planks are not even proposed as policy, yet the adoption of a platform remains an integral part of national conventions.

Although conventions gave at least the appearance of a more open selection process, the 1912 Republican Convention was an early example of an increasing demand for the formation of a primary election system to determine delegate support and party nominees. Theodore Roosevelt, troubled by policies he viewed as overly conservative on the part of his successor, President William Howard Taft (1857–1930), decided to challenge Taft for the Republican nomination in 1912. Roosevelt campaigned in states holding presidential primaries, and swamped Taft everywhere, including the incumbent’s home state of Ohio. Taft, however, still controlled enough delegates to carry him to victory at the convention and was the party nominee despite Roosevelt’s electoral strength. Roosevelt and his supporters (who chanted Thou shalt not steal! after Taft was nominated) fled to form a third party, and took enough Republican support away from Taft to help make Woodrow Wilson (1856–1924), the Democratic nominee, the next president. No such drama has occurred at modern conventions. The last nomination in doubt during a national convention was the 1976 Republican Convention, in which former California governor Ronald Reagan (1911–2004) nearly toppled incumbent President Gerald Ford (1913–2006). History was made at the 1984 Democratic National Convention when the party nominated the first female candidate for the vice-presidency, Geraldine Ferraro (b. 1935), though her selection was not a surprise before the convention convened.

CONVENTIONS AND THE PRIMARY SYSTEM

Since 1936, every successful presidential candidate has been nominated by his party convention on the first ballot. The advent of television and live coverage of conventions by the major networks, however, did capture some of the traditions of old. Conventions in the 1950s and
early 1960s retained the spectacle of the delegates choosing the ticket, and often the presidential nominee would throw the choice of his running mate to the convention floor. At the 1956 Democratic Convention, Adlai Stevenson (1900–1965) let the delegates choose and a dramatic race ensued between Senator Estes Kefauver (1903–1963) and Senator John F. Kennedy (1917–1963). Kennedy lost, but the nation watched as he delivered a graceful concession speech that many believed propelled him as a favorite for the 1960 nomination, which he eventually won. Even in 1960, though, Kennedy had to fend off a convention-week challenge from Lyndon B. Johnson (1908–1973), who did not participate in primaries as Kennedy had. Johnson was eventually the vice-presidential nominee.

Demand for a national primary system for choosing presidential nominees reached its peak at the 1968 Democratic National Convention in Chicago, Illinois. Senator Eugene McCarthy (1916–2005) of Minnesota had won much primary support for his stance against the Vietnam War and the increasingly unpopular incumbent Democratic president, Lyndon B. Johnson. Johnson, who declined to run for reelection, favored his vice president, Hubert H. Humphrey (1911–1978), who controlled the delegates and won the nomination. Humphrey’s nomination and his alliance with Chicago mayor and political boss Richard J. Daley (1902–1976), whose Chicago police forcefully repelled antiwar demonstrations throughout the convention—all of it seen on live television across the country—led to the formation of a committee that revamped the nominating process of the Democratic Party in favor of primary elections preceding the national convention. The Republican Party followed suit.

The Democratic and Republican parties, of course, differ in how they allocate delegates to the national convention. Democrats divide delegates according to how each state voted in the previous three elections; party leaders and certain elected officials hold 15 percent of the total number of delegates. Republicans assign delegates who are already pledged to vote for a certain candidate in proportion to the votes the candidates received in the primaries. The primary election season begins in January of the election year, usually with the New Hampshire primaries and Iowa caucuses (in which voters gather in schools, homes, and community centers to debate and vote), and continues in many other states until June. Most of the primary votes are cast before April, and the nominations of each party are not in doubt by the time the last primaries are held.

While the primary system is a more democratic method for selecting a presidential nominee in that it places the selection in the hands of voters rather than convention delegates, it has relegated the nomination function of the national convention to mere formality. Reliance upon the primary system to find a party’s presidential nominee has meant that presidential campaigns now begin two and sometimes three years ahead of the date of the election, and candidates are obliged to raise millions of dollars in campaign contributions to remain competitive in such a long process. The amount of money that changes hands during a presidential election has led many lawmakers and commentators to call for more legislation governing the influence of campaign contributions on candidates and officeholders. However, few—if any—in either major party have suggested a return to the convention as the sole nomination process. Thus conventions have taken on a role of showcasing important members of the national party, writing and adopting a party platform, and presenting the presidential and vice-presidential nominees, who give acceptance speeches that attempt to persuade the voting public to support their campaigns.

POLITICAL CORRECTNESS

The term political correctness was first used in the innumerable and acrimonious discussions among Communist ideologues that took place, both in Russia and among members of Communist parties abroad, after the Bolshevik Revolution of 1917. The term was used, with-
out any irony, to judge the degree of compatibility of one’s ideas or political analyses with the official party line in Moscow. Because the Kremlin position kept twisting in response to nationalist and personal interests much more than to ideological consistency, staying politically correct required agile intellectual gymnastics.

After the demise of international Communism around 1990, when there no longer was a correct, official line to be measured against, political correctness took on a second life as a term of derision used mostly by ideologues on the Right. The term was now meant to ridicule or stigmatize conformity with the opinions, or simply the vocabulary, of liberal or leftist intellectuals, mostly in academic circles. The principal targets of that ridicule were generally movements aiming to reduce prejudice and stigmatization against racial and ethnic groups, women, homosexuals, people with disabilities, and other marginalized groups.

Since the most noticeable change brought by such movements was the adoption and diffusion of neologisms and euphemisms aimed at enfranchising such groups, the semantics of tolerance became the main butt of ridicule, notably “gender-neutral” language (e.g., chairperson); the use of new ethnic labels (such as Native American for American Indian, Roma for Gypsy, or Inuit for Eskimo); or euphemisms (such as differently abled for disabled, or educationally challenged for slow learner).

Soon, however, the critics of political correctness extended the scope of their attacks from the relative trivia of semantics to what they saw as a stultifying climate of hypocrisy and conformity, rampant, they alleged, on college campuses. Political correctness, they argued, stifled intellectual discourse in and out of academia, or, worse, punished the pursuit of legitimate research on, for example, the genetic bases of human behavior, sexual orientation, or gender differences.

Some scholars found themselves under assault from both the Left and the Right. For instance, the few social scientists who tried to suggest (and show) that human behavior was the product of biological as well as cultural evolution were simultaneously berated as “secular humanists” by fundamentalist Christians and as racist and sexist by their colleagues in the mainstream of their disciplines.

Intellectual climates keep changing, however, so that what may appear to be the menacing shadow of political correctness from the Left may eventually be neutralized by a rising tide of conservatism from the religious Right and the “intelligent design” movement. Reason and sanity, it seems, are always under attack, from the Left, from the Right, or, indeed, from both simultaneously. The university campus is the main theater for such jousts, and thus, also, the main depository of much nonsense. In the end, each swing of the ideological pendulum leaves a little residue of good sense. We must, however, be vigilant that the university remains the one venue where anything can be said fearlessly, and, thus, where political correctness has no place. Any restriction on intellectual discourse, even when internally generated, clashes with the central mission of the university, namely the critical examination of ideas and the diffusion of knowledge.

**POLITICAL CULTURE**

Although insights into political culture have been part of political reflection since classical antiquity, two developments in the context of the French Revolution laid the groundwork for modern understandings. First, when members of the Third Estate declared “We are the people,” they were overturning centuries of thought about political power, captured most succinctly by Louis XIV’s infamous definition of absolutism: “L’état, c’est moi” (“I am the State”). Henceforth, sovereignty was seen to reside in society rather than in the monarch and his divine rights. A century later, Max Weber turned this political claim into a scientific one when he defined legitimacy as that which is considered to be legitimate—not only by elites but by the population in general; to understand the political power of the state, social science must therefore attend to its reception and sources in society. Second, when Jean-Jacques Rousseau retheorized the social contract as one in which individual interests were taken up in an overarching “General Will” of the collective, he raised the question of how social solidarity could be maintained in the absence of recourse to divine right. His answer was “civil religion,” symbols and rituals that establish and dramatize the sense of collective belonging and purpose. A century later, Émile Durkheim took up these themes when he questioned whether modern, complex societies could generate sufficient solidarity to function in a stable manner. Durkheim’s interest in what he called collective effervescence (generated in and through communal rituals) and collective representations (embodied in symbols as well as more abstractly in “collective conscience”) extended Rousseau’s concerns and has underwritten con-
temporary analyses of political culture as the sets of symbols and meanings involved in securing and exercising political power.

Contemporary work on political culture, however, dates more directly to the mid-twentieth century, particularly in the United States. In the wake of World War II (1939–1945), social scientists were motivated to explain why some nations had turned to authoritarianism while others supported democratic institutions. Before and during the war, anthropologists such as Margaret Mead and Ruth Benedict were proponents of a “culture and personality” approach, which asserted that members of different societies develop different modal personalities, which in turn can explain support for different kinds of political programs and institutions. In a somewhat different vein, the German exile philosopher Theodor Adorno and colleagues undertook a massive study during the war into what they called, in the title of their 1950 work, The Authoritarian Personality, continuing earlier research by critical theorists into the structure of authority in families, which they believed had led Germans to support authoritarian politics and social prejudice. In a similar vein, Harold Laswell described a set of personality traits shared by “democrats,” including an “open ego,” a combination of value-orientations, and generalized trust.

Perhaps the most important work on political culture in this period was Gabriel Almond and Sidney Verba’s 1963 The Civic Culture: Political Attitudes and Democracy in Five Nations, which combined Laswell’s description of the democratic personality with at least two strands of social science theory at the time. First, the predominant sociological theory in the United States was that of Talcott Parsons, who explained social order in terms of institutions that inculcated individuals with coherent sets of norms, values, and attitudes—what Parsons called culture—which in turn sustained those institutions through time. In contrast, the so-called behavioral revolution in political science argued that such accounts neglected extra-institutional variables as sources of social order (a concern that could be traced back to Montesquieu in the mid-eighteenth century, who sought external factors—in his case climate—to explain the different forms of law in history); in Parsons, moreover, critics charged that norms, values, and attitudes were more often simply assumed as necessary integrative features of social systems rather than measured empirically (hence the appeal to behaviorism, which in psychology held observability to be the only relevant criterion for science).

The major point of Almond and Verba’s comparative study was to address the role of subjective values and attitudes of national populations in the stability of democratic regimes. This fit clearly within the behavioral revolution because it turned to extra-institutional variables (norms, values, and attitudes) to explain political outcomes. Nonetheless, the work was presented as a study of political culture, defined as the aggregate pattern of subjective political dispositions in the populace, thus incorporating and, indeed, operationalizing, the Parsonsian concept of culture. On the basis of extensive survey research, The Civic Culture theorized three basic orientations toward political institutions and outcomes: parochial, where politics is not differentiated as a distinct sphere of life and is of relatively little interest; subject, in which individuals are aware of the political system and its outcomes but are relatively passive; and participant, where citizens have a strong sense of their role in politics and responsibility for it. The Civic Culture rated five countries on these qualities, finding Italy and Mexico to be relatively parochial, Germany to be subject, and the United States and the United Kingdom to be participant political cultures.

Subsequent work in this tradition by Ronald Inglehart and others has shown that the effect of basic satisfaction with political life and high levels of interpersonal trust (what would later be called “social capital”) are analytically distinct from economic affluence, thus arguing forcefully that democracy depends on cultural as well as economic factors. Contemporary authors such as Samuel Huntington have extended this kind of argument about norms, values, and attitudes to the world stage, where they describe a “clash of civilizations” in terms of basic “cultural” differences understood in this way.

Nevertheless, there have been many criticisms of the approach developed by Almond and Verba and their colleagues. These ranged from methodological concerns about the survey instruments to the claim that the approach normatively privileged American-style democracy as the model against which all others must be judged. Still others argued that political culture was being used as a residual category for all that cannot be explained by other theories, and thus has no theoretically defensible conceptual ground of its own. Most trenchant, however, were charges that the way Almond and Verba defined political culture—in terms of subjectivity—eviscerates the importance of culture as symbols and meanings: Without a richer understanding of symbols, meanings, rituals, and the like, critics charged, political culture could not be distinguished conceptually from political psychology: “What ‘theory’ may be found in anyone’s head is not,” one set of critics charged, “culture. Culture is interpersonal, covering a range of such theory…. Political culture is the property of a collectivity” (Elkins and Simeon 1979, pp. 128–129).

Indeed, since the 1970s, political culture theory has been radically transformed by a more general cultural turn in social science, brought about by such influences as the symbolic anthropology of Clifford Geertz and the rise of semiotics, structuralism, and poststructuralism in European
anthropology and literary theory. In contrast to older subjectivism, as well as to those who ignore culture altogether, newer work on political culture in the 1980s and 1990s argued that, in Geertz's words, "culture is public because meaning is" (Geertz 1973, p. 12). This work reformed political culture as a system of meanings sui generis, as "a form of structure in its own right, constituted autonomously through series of relationships among cultural elements" (Somers 1995, p. 131), or as "codes," which could be either manifest or "deep." In this view, political culture can be measured only crudely by survey analysis; instead, it must be excavated, observed, and interpreted in its own terms as an objective structure, on the analogy of language.

However, the rise of various structuralisms in political culture analysis—emphasizing the Rousseau-Durkheim more than the Montesquieu-Weber axis—has required some modifications since the 1990s, when structuralist approaches in general have fallen somewhat out of favor. More recently, many historians, sociologists, and anthropologists have embraced a "practice" approach that emphasizes meaning making rather than meaning systems. While in no way a return to the earlier subjectivism in political culture theory, the practice approach recognizes the limitations of structuralism, in which agents seem to drop out of the picture, or serve only as enactors or carriers of structure. Instead, recent work has emphasized "the activity through which individuals and groups in any society articulate, negotiate, implement, and enforce competing claims they make upon one another and upon the whole. Political culture is, in this sense, the set of discourses or symbolic practices by which these claims are made" (Baker 1990, p. 4).

In sum, political culture theory makes empirical sense out of the French Revolution's claim that sovereignty derives from society rather than the state. One temptation with this recognition, however, is to assume that while states are about power, societies are about meaning and the reception of power. One solution, inspired by Michel Foucault, among others, has been to declare society the true locus of power. The problem is that this misses the ways in which states do indeed set agendas for societies. Recent analyses have thus returned to the political culture of the state (e.g., Bonnell 1997). But they do so without supposing that societies are mere recipients of such productions.

In contrast to much work in political sociology, which has drawn a facile distinction between "merely" symbolic politics and "real" politics, recent political culture theory has thus demonstrated that social life is an ongoing reproductive process. New political culture analysts in particular have focused not only on how political acts succeed or fail to obtain some material advantage but also on how in doing so they produce, reproduce, or change identities. The struggle for position that constitutes politics, we now understand, is always simultaneously strategic and constitutive: As Lynn Hunt has written, "Political symbols and rituals were not metaphors of power; they were the means and ends of power itself" (Hunt 1984, p. 54). Interpreting them and understanding how they are generated and how they work is thus of paramount importance.

POLITICAL DEVELOPMENT

SEE Research, Democracy.

POLITICAL ECONOMY

The phrase political economy came into currency in the seventeenth and eighteenth centuries. It is natural to think that the name refers to a discipline that studies how politics affects the economy and vice versa. Yet the fundamental idea of the original political economists—Adam Smith, David Ricardo, Thomas Malthus—was that an
economy works best when governed least. They believed that there were economic principles that tended to produce the common good if government generally left people alone in their material endeavors. Adam Smith’s (1776) famous remark about “the invisible hand” puts the idea succinctly: an individual, through his industry, intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention. … By pursuing his own interest he frequently promotes that of the society more effectually than when he really intends to promote it. (p. 456)

This invisible coordination of individual interest will result in the general welfare only if government allows the market to run on its own principles. It is ironic that the founders of political economy—the “classical economists,” as they are now called—rejected a large role for politics in the economy.

While there is irony in calling this view political economy, it nonetheless has a rationale. The term economics derives from the Greek word for “household.” For much of human history, the individual household was expected to meet the needs of its members through its own efforts, without significant help from the state. Nation-states came into being only in the sixteenth and seventeenth centuries, and they were soon expected to have the ability and duty to improve economic well-being. Mercantilist and physiocratic theories were the first expressions of this concern. Both of these, but especially mercantilism, demanded significant intervention in the economy, including protectionist measures to improve a nation’s balance of trade.

The political economists reacted to these earlier theories. Their aim was to reveal the proper aim of political activity in economic life. The name political economy still made sense for their discipline, even though the proper aim was negative, a matter of minimizing interference.

MARXISM
The next iteration in the life of the phrase political economy came with the work of Karl Marx in the mid-nineteenth century. For Marx, the economy dominates politics. In every era (until the final era of communism) there is an economic structure that benefits certain classes and exploits others. The rest of social life, including the state, the law, culture, and dominant ideas and values, exists only to promote the economic structure and to further the interests of those on top. Marx is reasonably categorized as a political economist, given the linkage he sees between economics, politics, and the rest of social life.

There is, however, another irony about the use of the phrase political economy here. Marx’s most important economic work, Capital, is subtitled A Critique of Political Economy. His central ideas about society are most clearly laid out in the famous preface to a different work entitled A Contribution to the Critique of Political Economy. Marx thus took himself to be rejecting political economy. He was rejecting (“critiquing”) the ideas of the classical economists such as Smith and Ricardo. Nevertheless, since he linked economy, politics, ideology, and culture, it became reasonable for later generations to think of Marxism as the archetype of political economy. For many today, political economy means Marxist and nonorthodox explanations of political, legal, and cultural phenomena, and also mainstream ideas by reference to the economic forces they are said to uphold.

NEOCLSASICAL ECONOMICS
By the end of the nineteenth century the phrase political economy gave way to the word economics. Marginal utility theory, also known as neoclassical economics, developed. Perhaps the strongest ground for the name change was the desire to develop a discipline both independent and scientific, based on the rigorous mathematical tools and laws that marginal utility theory put forth to explain production and exchange. Neoclassical economic thinkers wished to disentangle their discipline from the normatively tinged areas of politics, philosophy, and the moral sciences generally. Thus the concept of political economy slowly gave way to the more scientific-sounding idea of economics. The phrase political economy has, however, remained in favor among those who want to resist the narrowness of modern neoclassical economic theory and insist that economic phenomena can only be fully understood through an understanding of the roles played by politics and culture.

Another use of the term political economy has developed in the last half century in the work of public choice theorists such as James Buchanan, Gordon Tullock, and Mancur Olson. These scholars seek to explain the behavior of groups, especially governments, on the basis of the idea, central to modern economic theory, that people tend to act as individual utility maximizers. Roughly put, public choice theorists argue that through the political process, politicians attempt to capture benefits for specific groups from the resources of the population generally ("rent seeking"). Thus, citizens are taxed to pay for benefits they do not receive, and the economy is made inefficient. Public choice theorists tend to respond to this “government failure” by returning to the original idea of the classical economists—the less government the better.

In recent years, the idea of political economy has come into use among those interested in global problems. International political economy studies national development and the planetary distribution of wealth. It examines the effects of economic globalization on human well-
being, politics, law, culture, the environment, national sovereignty, and religion. Perhaps the most important question is the effect of economic globalization on the rich and poor. Thinkers scrutinize such organizations as the International Monetary Fund, the World Bank, and the World Trade Organization. Some argue that these represent a modernized version of neoclassical economics, labeled neoliberalism, that tends to work in favor of the rich and powerful and against the weak and poor. Others argue that free trade and liberalized flows of capital and labor will eventually improve the prospects of the global poor. The continuing debate about these issues gives political economy a new meaning in the global context.

POLITICAL INEQUALITY

SEE Inequality, Political.

POLITICAL INSTABILITY, INDICES OF

Political instability can be defined in at least three ways. A first approach is to define it as the propensity for regime or government change. A second is to focus on the incidence of political upheaval or violence in a society, such as assassinations, demonstrations, and so forth. A third approach focuses on instability in policies rather than instability in regimes (i.e., the degree to which fundamental policies of, for instance, property rights are subject to frequent changes).

INDICES OF POLITICAL STABILITY

Just as there are a number of definitions of political instability, there are also a number of indices designed to measure the level of political instability in countries. Some of these indices have been developed primarily for academic or policy purposes, such as the POLITY indices and the World Bank governance indices. The inclusion of objective data on political violence, such as the number of assassinations and demonstrations, in data sets for academic studies is common.

There are a number of other indices that have been developed primarily to inform international investors of the political risk involved in investing in various countries. A number of companies and institutions offer these types of indices; they include the Political Risk Services (PRS) group's International Country Risk Guide [ICRG] indices; Business Environment Risk Intelligence (BERI); the Economist Intelligence Unit; Moody's and many more.

Finally, there are a number of more specialized indices of phenomena that relate to political instability, such as the Corruption Perceptions Index of Transparency International, and the political risk and civil liberties indices of Freedom House.

The available indices relate to the various definitions of political instability in different ways. The POLITY data contain indices of regime transition and durability, reflecting the first definition. The objective indices of political violence included in the 1997 dataset of William Easterly and Ross Levine are more in line with the second definition. Indices such as those in the ICRG encompass several of the definitions, including instability in terms of potential policy volatility.

The indices broadly fall into two categories in terms of how they are developed. On the one hand there are the objective indices, which typically collect count data on the incidence of certain phenomena (e.g., demonstrations, revolutions, assassinations, and more). On the other hand, perceptions indices, which use expert opinion or surveys, gauge the assessments and insights of certain groups on the degree of political stability in a country.

PERCEPTIONS INDICES

The design of objective indices of political instability does not require much explanation. For perceptions indices,
however, the methodology must be examined more closely. Following is a detailed account of two sets of indices that are frequently used in academic studies; the ICRG indices and the World Bank governance indices developed by Daniel Kaufmann and his colleagues.

The ICRG rating comprises three subcategories of risk: political, financial, and economic. The political risk rating includes twelve weighted variables covering both political and social attributes. The twelve variables are: government stability; socioeconomic conditions; investment profile; internal conflict; external conflict; corruption; military in politics; religious tensions; law and order; ethnic tensions; democratic accountability; and bureaucracy quality. The score on each variable is set by experts based on available information, and is thus based on subjective judgment. The ICRG indices provide monthly data for 140 countries, starting in 1984.

The World Bank governance indices measure six dimensions of governance: voice and accountability; political instability and violence; government effectiveness; regulatory quality; rule of law; and control of corruption. The index of political instability and violence measures the likelihood of violent threats to, or changes in, government, including terrorism. The indices are based on 352 individual variables measuring perceptions of governance, drawn from thirty-seven separate data sources constructed by thirty-one organizations. The sources include inter alia the ICRG indices. The governance indices cover 209 countries and territories for 1996, 1998, 2000, 2002, and 2004.

USE OF INDICES IN ACADEMIC WORK
Indices of political instability are employed in many cross-country empirical studies, which are generally of two types. In one type of studies, political instability is the dependent variable, whose variation is explained by other variables. These kinds of studies are typically conducted in the discipline of political science. In other studies, political instability is an independent variable. This type of analysis is common in the field of economics, where political instability is related to such dependent variables as growth or investment.

In the first type of study, researchers, for instance, seek to establish a link between inequality and political instability. Early studies of this kind use objective indices of political violence as their dependent variable. In later studies such as that of Philip Nel in 2003, objective indices of violence are complemented by the Kaufmann political stability index.

A similar development is apparent in economic studies using political instability as an independent variable. Such studies have shifted emphasis from analyzing political stability in the traditional sense towards institutions. Early studies of growth, such as the 1992 work of Levine and David Renelt, find that the number of revolutions and coups has a robust influence on investment, which in turn influences growth. Daron Acemoglu and his colleagues used indices from the PRS group and POLITY to test the impact of institutions on growth. In the investment literature, Alberto Alesina and Roberto Perotti and Jakob Svensson use indices of political unrest and violence, and indices of government change, as independent variables. Aymo Brunetti and Beatrice Weder, however, include both objective measures and perceptions indices such as those of the ICRG. Moreover, in early-twenty-first century studies of foreign direct investment (FDI), researchers frequently use perceptions indices. Steven Globerman and Daniel Shapiro use the Kaufmann governance indices to explain the pattern of FDI across countries, while Philipp Harms and Heinrich W. Ursprung use a set of ICRG indices for the same purpose.

Political Parties

Political parties are organizations subscribing to an ideology or formed around a special interest, with the aim of attaining power within government. They participate in elections, select candidates for public office, mobilize voters, raise funds, articulate political positions, coordinate policy making, develop campaign strategies, and generate symbols of party identification and loyalty. Parties are rooted in political, religious, sectional, ethnic, racial, and/or economic class interests. Parties are frequently coalitions of groups espousing disparate interests. Persons who support a party’s candidates, espouse its policies, and work to advance its political objectives are partisans. An opposition party does not challenge the legitimacy of the government, but only its policies.

Early Political Parties

European political parties formed during the seventeenth and eighteenth centuries to advise the monarchy. The model of a political party can be traced to Great Britain as the Tory and Whig parties fought for control of Parliament. Alexander Hamilton (1755–1804) founded the first U.S. political party, the Federalists, in 1792 to support his fiscal and political policies.

Although a competitive party system is considered to be an essential prerequisite for political freedom today, seventeenth- and eighteenth-century Anglo-American thinkers were wary of political parties, faulting them for serving special interests rather than the public good. Parties often were associated with treason and conspiracy. George Washington (1732–1799), the first president of the United States, in his “Farewell Address” deplored “the baneful effects of the Spirit of Party” (Washington 1796, p. 226). John Adams (1734–1826), the second president, held that “a division of the republic into two great parties … is to be dreaded as the greatest political evil under our Constitution” (Adams 1851, p. 508). Political leaders who serve only the interests of their parties rather than the common good were condemned as corrupt. The Federalists and Jeffersonian Republicans did not regard each other as legitimate opposition parties, but as threats to the republic that should be eliminated. When the Federalist Party collapsed in 1814, the political consensus that ensued—the “Era of Good Feeling”—was cited as evidence that the U.S. system had succeeded.

Others wrote more sympathetically and prophetically about the positive role that parties played in political life. Edmund Burke (1729–1797) saw party competition as a necessary good. Famously defining a party as “a body of men united for promoting by their joint endeavors the national interest upon particular principle in which they are all agreed,” Burke declared that “[p]arty divisions whether operating for good or evil are things inseparable from free government” (Burke 1925, p. 229). One of the authors of the U.S. Constitution, James Madison (1751–1836), following the English philosopher David Hume (1711–1776), held in Federalist Paper number 10 that parties, or “factions,” could not “be removed” because they are rooted in man’s natural propensity to differ. The “mischief” of factions that cause, though, could be curbed by fostering a multiplicity of “factions and parties” that would render unlikely “that a majority of the whole will have a common motive to invade the rights of citizens.” If they do, sufficient impediments, such as bad roads and poor communications, would make it difficult for them “to act in unison” (Madison 1787, pp. 55–61).

Although there is no mention of political parties in the U.S. Constitution, political parties are a logical outcome of the constitutional system. The First Amendment of the Constitution guarantees freedom of speech and assembly, both necessary conditions for the emergence of voluntary political organizations. The Constitution’s delegation of legislative power to elected representatives encouraged the formation of political parties. Parties, in turn, transformed and democratized the constitutional system. Thomas Jefferson (1743–1826) is credited with having created the first popular political party—the Democratic-Republicans later known as the Democratic Party. For his election to the presidency in 1828, Andrew Jackson (1767–1845) transformed this party into the first national, massed-based party.

Types of Parties and Party Systems

Because power is shared between the central government and the individual states, the U.S. federal system of government impedes the development of the type of unified, cohesive parties found in, for example, the European parliamentary systems. A parliamentary system demands greater party discipline because the majority party in Parliament forms the government. Except when the Democrat and Republican parties gather every four years...
at their national conventions to nominate candidates for the offices of president and vice president and to write their platforms, they are not in any meaningful way national parties. Rather, each is really a coalition of state parties that are themselves confederations of semiautonomous local governmental parties. Even presidents or candidates for the presidency have only feeble control over state and local party members and elected officials. Under the U.S. system, a divided government is possible, when one or both houses of Congress and the presidency are held by different parties.

The ideological spectrum of political parties typically runs from left to right. Right-wing political parties espouse conservative or reactionary views, whereas left-wing parties are associated with progressive or radical policies. The Conservative Party of Canada and the United Kingdom and the Republican Party of the United States are right-wing parties, and the Labour Party of the United Kingdom, the Liberal Party of Canada, and the Democratic Party of the United States are generally considered to be left-wing parties. The British National Front Party and the Front National of France are examples of far right-wing parties, and the Green, Communist, and Socialist parties are all on the extreme left.

Political party systems vary across the world. Nonparty states, such as Saudia Arabia and the United Arab Emirates, have no political parties at all. Single-party states, such as the People's Republic of China, North Korea, and Cuba, allow only one-party rule. The constitution of the former Soviet Union officially established the primacy of the Communist Party. The prohibition against the formation of opposition parties is evidence of the absence of liberty. In contrast, dominant-party states do allow other parties, but one party, such as the People's Action Party of Singapore and African National Congress Party of South Africa, typically wins most if not all elections. In the U.S. South until the 1970s, the Democratic Party won nearly all the general elections.

Two-party states, such as the United States, have two dominant national parties that vie for power. The system for electing the president in the United States entails an indirect election in which the electorate votes for a slate of electors who cast their votes for the president and vice president in an electoral college. This system impedes the formation of third parties: Because the slate of electors for the electoral college are elected in winner-take-all state elections, minor party candidates rarely win sufficient electoral college votes to have an impact on a national election. The election of legislative representatives in winner-take-all district elections further discourages the development of third parties. The principle that the single-member district plurality voting system results in a two-party system has been called Duverger's law, after the French sociologist, Maurice Duverger (b. 1917), who formulated it. The two parties tend to resemble each other because each party gravitates toward the middle in an effort to capture the independent vote.

Multiparty states, such as the United Kingdom, Israel, and Canada, have a number of parties that compete for power. A multiparty system commonly exists in states with a parliamentary form of government. If no party wins a majority of seats in a parliamentary election, a coalition government is formed between two or more parties. The majority of the members of Parliament vote for a leader who serves as the head of the government. Proportional Representation, a scheme of voting used in several European states, encourages further proliferation of parties. Under this system, legislative seats are allocated according to the percentage of popular votes that the party received in the most recent election.

POLITICAL PARTIES AND DEMOCRACY

Modern political scientists regard political parties as beneficial avenues through which political interests and opinions can be channeled. “Democracy,” political scientist E. E. Schattschneider (1892–1971) concluded, “is unthinkable save in terms of parties” (Schattschneider 1942, p. 124).

Other thinkers, though, were more cautious in their assessment of the democratic influence of political parties on government. Most significantly, the Italian anarcho-syndicalist sociologist Robert Michels (1876–1936) proposed the iron law of oligarchy which stipulated that no matter how democratic an organization may be initially, it will eventually develop into an oligarchy. All large organizations, to attain greater efficiency and decision-making coordination, tend to concentrate power into the hands of a few. As parties grow in size and complexity, they become more hierarchically organized. True democracy, given the premises of Michels’s argument, is practically and theoretically impossible.

The noted American sociologist C. Wright Mills (1916–1962) observed that the top of the American political system was becoming more unified and powerful. He described in his most famous book, The Power Elite (1956), the interconnecting relationship between corporate, military, and government leaders. His controversial argument was that there was a growing power gap between a class of people Mills called “the power elite” and the increasingly manipulated and controlled masses.

Not all theorists agreed with the pessimistic implications of these arguments. The popular definition of democracy as “government by the people,” Schattschneider contended, exaggerates the power of the public. Rather, a more realistic definition that emphasizes organ-
ization and leadership rather than spontaneous grass-roots politics is needed. “Democracy is a competitive political system,” he observed, “in which competing leaders and organizations define the alternatives of public policy in such a way that the public can participate in the decision-making process” (Schattschneider 1960, p. 141).

WEAKENING OF PARTY LOYALTY
Some of the factors that weaken the power and influence of political parties include declining patronage, the direct primary, the role of the media, the proliferation of non-partisan political action committees, and the growing importance of the Internet as a tool for raising campaign funds and disseminating information about candidates and issues. The direct primary diminishes the ability of party leaders to select preferred candidates to run for political office. Patronage induces voters to support the party’s candidates by handing out jobs, contracts, or promotions for political reasons rather than merit. As easily accessible information about candidates and issues becomes available to voters through the mass media and the Internet, voters become less dependent on parties. Better informed voters tend to be less deferential to parties and more likely to split their votes among candidates from two or more parties.

Many analysts of the U.S. political party system detect a continuing trend toward party dealignment. A growing number of voters are declining to affiliate with any political party, preferring instead to identify themselves as independents. Since 1988 the plurality of independent voters has steadily increased. In 2004 39 percent of the American voters identified themselves as independents. Polls suggest that a large portion of the American public is allergic to partisan politics. They want candidates who promise to rise above partisan bickering and party loyalty to work on enacting legislation that will effectively solve the nation’s most pressing social and economic problems.

The most important function of the national political parties today is to raise funds for candidates and wage “get-out-the-vote” campaigns.

POLITICAL PSYCHOLOGY
Political psychology is an interdisciplinary academic field that emphasizes the psychological dimension of political life. Its practitioners use psychological constructs, such as personality, attitudes, beliefs, values, needs, goals, and expectations, to explain political behavior and to examine the complex and reciprocal relationship between politics and psychology. Political psychologists presume that political actions, like all other forms of human behavior, are the result of interplay between the individual and the environment. Because the scientific study of politics investigates relations and interactions among individuals behaving as political actors, it is inevitably linked with
psychology, which is concerned with human thinking and behavior. Political analysts throughout the ages and across civilizations have been interested in the interrelation between personality traits and political contexts. They have employed many concepts and theories to explain why rulers and subjects think and act as they do, and how their thoughts and actions shape the course of politics. Hence, political psychology focuses on the important role of psychological factors in determining the individual's responses to various contextual/environmental stimuli.

Born in the decades between World Wars I and II, modern political psychology has developed to cover a wide variety of subjects. It traces its intellectual roots back to the eminent American political scientist and communications theorist Harold D. Lasswell (1902–1978). His classic writings, such as *Psychopathology and Politics* (1930), *World Politics and Personal Insecurity* (1935), *Politics: Who Gets What, When, and How* (1936), *Power and Personality* (1948), and *Power and Society* (1950), centered on the impact of individual and social psychological processes—perception, motivation, conflict, cognition, learning, socialization, attitude formation, and group dynamics—as causal factors influencing politics. It was Lasswell's pioneering work in political psychology that contributed to the field's initial unidirectional nature, characterized by a specific focus on how the individual psyche shapes political behavior and values.

Several leading members of the Institute for Social Research at the University of Frankfurt (the so-called Frankfurt school) who had arrived in the United States as refugees from Nazi Germany—Max Horkheimer (1895–1973), Erich Fromm (1900–1980), Herbert Marcuse (1898–1979), and Theodor Adorno (1903–1969), among others—developed the concept of authoritarian personality, which deals with the causal relationship between political views and personality types. Their ideas inspired Adorno and his associates at the University of California at Berkeley to conduct a seminal empirical study, *The Authoritarian Personality* (1950), based on the F(ascism)-scale measurement, which linked right-wing authoritarianism (“implicit antidemocratic tendencies and fascist potential”) to a family pattern of rigidity, discipline, strict rules, and fearful subservience to the demands of parents. Even though it has been widely criticized, including for its heavy reliance on the psychoanalytical perspectives of Freudian theory, this now classic work reveals how certain politically relevant aspects of the psyche lead to fascist or authoritarian belief systems. The F-scale describes a personality type characterized by ethnocentric nationalism, extreme in-group conformity, rigid adherence to conventional values, submissiveness to authority, a readiness to punish, opposition to the free-thinking and kind-hearted, arrogance toward those considered inferior, and other authoritarian attitudes that explain major political outcomes (for instance, the rise of archconservative, ultranationalist, and fascist ideologies and war in twentieth-century Europe).

Political psychology received a significant impetus from and, in turn, was a major contributor to the “behavioral revolution” that swept the field of political science in the 1950s and 1960s. Behavioral-oriented researchers directed their scholarly attention to new issues such as analyzing the impact of personality characteristics upon political participation and party preference. Lasswell, for one, came up with eight psychological reasons for participation in politics: power, wealth, well-being, skill, enlightenment, affection, rectitude, and respect. Similarly, Robert E. Lane in his *Political Life: Why and How People Get Involved in Politics* (1965) argued that political participation serves a number of conscious and unconscious needs and motives, including power, economic and material gain, friendship and affection, self-esteem, relief from psychic tensions, and a need to understand the world. Thanks to the behavioral revolution, survey methods showed marked improvement from early studies such as *The People's Choice* (1944), the classic study of the 1940 U.S. presidential election conducted by the famous Austrian-born sociologist Paul F. Lazarsfeld (1901–1976), to later ones such as *The American Voter* (1960), the best-known research study of American voting behavior by Angus Campbell, Philip Converse, William Miller, and Donald Stokes. Electoral behavior was examined in relation to various demographic and population variables (age, gender, level of education, type of employment, social class, ethnicity, race, religion, and ideology). The increased sophistication of public opinion polling led to numerous in-depth analyses of belief systems at both the mass and elite level, such as Philip Converse’s influential study, “The Nature of Belief Systems in Mass Publics” (in David Apter’s *Ideology and Discontent*, 1964), which found that mass public opinion tends to be inconsistent, fickle, and poorly informed.

Largely under Lasswell's influence, early political psychology had centered on the unidirectional impact of individual and social psychological processes upon the polity, but in later decades attention began to be devoted also to the reverse effect of politics on personality systems. Studies of political culture and political socialization, such as Gabriel Almond and Sydney Verba's *The Civic Culture: Political Attitudes and Democracy in Five Nations* (1963), looked at how political systems inform individual behavior and values. By the 1980s most political psychologists had accepted the “bidirectional” nature of the interaction between individual psychology and the polity:

>The perceptions, beliefs, motives, opinions, values, interests, styles, defenses, and experiences of individuals—be they citizens, leaders, group
members, bureaucrats, terrorists, or revolutionaries—are seen as influencing what they do politically; and, in turn, the political culture, political system, mechanisms of political socialization, political movements and parties, and the international system are perceived as having an impact on what people are like. (Hermann 1986, p. 2)

Political psychology finally took shape as an academic discipline in its own right when the International Society of Political Psychology was founded in 1978 and began holding annual scientific meetings and publishing a quarterly journal, Political Psychology. Today, political psychology is a key component of the political behavior subfield of political science. Its diverse objects of analysis range from the psychobiography of political leaders (for example, the 1997 psychobiography of President Richard Nixon by Vamik D. Volkan, Norman Itzowitz, and Andrew W. Dod) to inquiries into the “postmaterial” bases of identity politics (e.g., Ronald Inglehart’s seminal work, *Silent Revolution: Changing Values and Political Styles among Western Publics*, 1977). Psychological terminology is now an important and pervasive part of political science discourse, as numerous psychological concepts have been incorporated into political studies at both the national and international level. Psychological concepts are widely used in research on voting behavior, political socialization, political leadership, the dynamics of public opinion, political attitudes, political conflict and cooperation, international negotiation, decision-making, and, more recently, political information processing.

The two empirical research methods most often employed to study psychological variables are the sample survey and the in-depth interview. For example, political psychologists frequently use attitude surveys to probe the connections among personality structures, demographic and population variables, and dispositions toward political participation and party preference. Other more innovative but less frequently utilized research tools include simulation, projective techniques, content analysis, focus groups, and the controlled experiment. The application of psychological insights to political inquiry remains a widespread and growing trend, as many political psychology studies continue to appear within the framework of related social-sciences disciplines, especially political science. Although no underlying scientific paradigm or even a single basic theory provides unity and coherence to this eclectic interdisciplinary field, political psychology has already acquired a permanent, if rather heterogeneous and pluralistic, presence within the discipline of political science.

**POLITICAL SCIENCE**

The first efforts to systematically study politics can be traced to Plato’s *Republic* (c. 427–c. 347 BCE) and Aristotle’s *Politics* (384–322 BCE). Their works were later incorporated into Christianity through neo-Platonists, such as St. Augustine (354–430 CE), and neo-Aristotelians, such as St. Thomas Aquinas (c.1225–1274 CE). The classical and Christian traditions of political philosophy postulated metaphysical first principles and relied on a process of deductive reasoning that sought to derive the moral and ethical principles of an ideal-state. Whether the ideal-state was ever achieved by any civilization was considered secondary to discovering the “highest good” that ought to guide citizens and statesmen.

The political writings of Niccolò Machiavelli were the first to break with these traditions of political philosophy. Machiavelli believed that the study of political history could yield general principles to guide statesmen in the conduct of politics, diplomacy, and war. He studied...
existing and historical political institutions, and the actions of great statesmen, not for the purpose of discerning a morally ideal-state, but to identify institutional arrangements that would maintain social order and political stability. The separation of politics from any metaphysical or theological foundation led subsequent political philosophers to seek a new basis for legitimate political authority, although, in the end, solutions such as reason, natural law, custom, and tradition were supplanted by the idea that sovereignty resides in a nation's people.

FROM POLITICAL PHILOSOPHY TO POLITICAL SCIENCE
Francis Lieber (1798–1872) is considered the first modern political scientist. He was a liberal German émigré to the United States, who from 1827 to 1832 devoted himself to writing and editing the thirteen-volume Encyclopedia Americana. Its major contribution was to establish the idea of the state, or Staatswissenschaft, as the organizing concept of political science. The idea of the state was gaining wide currency in Europe, particularly in Germany, but it was Lieber who first argued in the United States that the "idea of the state is the basis of a class of sciences, and gives them a distinct character as belongs to the various classes of history, philosophy, theological, medical, &c., sciences" (1838, Vol. 10, p. 225). He drew a distinction between idea of the state and the "form of government," which was "merely a means of obtaining the great objects of the state" (1838, Vol. 11, p. 568). Against the backdrop of events leading up to the U.S. Civil War, Lieber articulated a distinctly idealistic theory of the state which identified the state as an abstract and organic sovereign society that was the source of governmental authority and the basis of its legitimacy. Lieber's appointment as professor of history and political science at Columbia University in 1857 made him the first person to hold that title in the United States.

THE DOMAIN AND METHODS OF POLITICAL SCIENCE
After Lieber, political science was established as a broader discipline when John W. Burgess, a professor of constitutional law, founded the Faculty of Political Science at Columbia in 1880. Burgess's school became the leading graduate faculty in political science during the 1890s along with the Department of History, Politics, and Economics, which had been established by Henry Baxter Adams at Johns Hopkins University in the 1870s. Burgess and Adams were both adherents of the Staatswissenschaft doctrine, but they shifted the discipline's methodological emphasis from political ethics to history.

In 1886 Columbia's faculty founded the Political Science Quarterly (PSQ), which was the new discipline's first scholarly journal. In its first issue, Edmund Munroe Smith, a professor of international law, announced that it would "recognize but one political science—the science of the state" (1886, pp. 2–3). However, the PSQ also facilitated a new departure in Staatswissenschaft by emphasizing that it was one thing to describe the state's development, comparatively and historically, but more was required to explain changes and development in the state. Smith argued "if we seek to trace through history the evolution of the state, we find each step in its development recorded in the evolution of law and explained to a great degree by economic changes" (p. 7). This methodological principle, which was called the economic interpretation of history was developed first by James E. Thorold Rogers (1823–1890), a professor of political economy at Oxford University, whose work stimulated the next advances in the discipline.

THE ECONOMIC BASIS OF POLITICS
The Populist revolt and the Progressive movement were fertile political environments for an intellectual revolt against the formalist-idealism of the early discipline. The method of economic interpretation led to a new iteration of Staatswissenschaft that seemed better able to explain the political conflicts of the era. During the 1890s, there were several miscues in the effort to define the method of economic interpretation, including both skirmishes and dialogues with Marxian historical materialists. The major breakthrough came from Edwin R. A. Seligman, a political economist in Columbia's Faculty of Political Science. Seligman's general statement of the economic interpretation of history is that:

The existence of man depends upon his ability to sustain himself; the economic life is therefore the fundamental condition of all life. Since human life, however, is the life of man in society, individual existence moves within the framework of the social structure and is modified by it....To economic causes, therefore, must be traced in the last instance those transformations in the structure of society which themselves condition the relations of social classes and the various manifestations of social life (1967, p. 3).

The method of economic interpretation was widely adopted by political scientists in the early twentieth century, particularly after Seligman had differentiated it from Karl Marx's historical materialism. Nevertheless, the method of economic interpretation is most often identified with the work of Charles A. Beard, one of Seligman's students, and the author of An Economic Interpretation of the Constitution of the United States (1913). In its political context, the book became an intellectual lightning rod,
because according to Beard capitalistic interests had dominated the U.S. Constitutional Convention of 1787 and, consequently, they authored a founding document that appealed “directly and unerringly to identical interests in the country at large” (p. 188). Beard later sought to generalize this doctrine in *The Economic Basis of Politics* (1922).

Beard exerted a powerful influence on the discipline over the next two decades, partly by authoring the first introductory textbook on *American Government and Politics* (1910), which became a standard text in political science for nearly four decades. In 1926, Beard’s soaring reputation secured his election as president of the American Political Science Association (APSA). By the mid-1930s, his economic interpretation of the American state had achieved orthodox status among scholars as the Great Depression forced economic considerations to the forefront of government and political science.

However, developments in political science and other disciplines put the doctrine of *Staatswissenschaft* under pressure from the outset. In 1895 the American Historical Association was established by historians seeking to institutionalize Leopold von Ranke’s methodological program of historical positivism. Frank J. Goodnow, who had been a member of *PSQ*’s editorial board, led the founding of the American Political Science Association in 1903, along with its new journal, the *American Political Science Review*. As the APSA’s first president, Goodnow reaffirmed that the domain of political science is “that political organization of society which is termed ‘the State’” (Ross 1991, p. 282). Nevertheless, the vision for a science of the state, anchored by political economy, started to fragment as one social science after another splintered into separate disciplines and, after World War I, began exploring the new positivist philosophy as an alternative methodological foundation.

**THE POSITIVIST MOVEMENT**

During the 1920s, political science began a paradigm shift that culminated in the behavioral revolution of the 1950s. The first aspect of this paradigm shift was a redefinition of the meaning of “science.” The positivist movement sought to place political science on the same methodological foundations as the natural sciences. This movement was also promoted by the federal government, which was anxious to bring about the same types of technical success in the social sciences as had been achieved in the physical, life, and behavioral sciences (psychology) during World War I. Positivists claim that all research is similar in method and differs only in the specific problems to be solved by a particular science. Thus, there is a single “scientific method” that starts with the formulation of a hypothesis, followed by empirical observation or experimentation, which leads to a falsification or verification of the initial hypothesis. Knowledge is accumulated incrementally as hypotheses are rejected or accepted as a result of empirical tests.

The Social Science Research Council (SSRC) was chartered in 1923 as an independent nonprofit organization, and funded by private foundations, specifically to encourage “behavioral research” in economics, sociology, and political science that employed empirical and statistical methods of the type advocated by positivists. The University of Chicago, which was among the first to pioneer such methods, was designated as the SSRC’s showcase institution. The SSRC distributed funds to political scientists and political science departments for fellowships and training in the new empirical methods, for the development of new courses in statistics and behavioral research design, and general department building along the Chicago model. Charles E. Merriam, a professor of political science at Chicago, is often called the father of behavioral political science. In his *New Aspects of Politics* (1925), Merriam called for a science based on the observation of real governments and political behavior, although he remained skeptical about an overly quantitative political science. This skepticism was retained by Harold D. Lasswell and V. O. Key, who were both students of Merriam and important transitional figures between the positivist movement of the 1920s and the behavioral revolution of the 1950s. Lasswell called for an applied political science oriented toward solving the problems of democracy as opposed to a discipline that emulated natural science in a quest to discover “universal laws” of political behavior without respect to their practical applications. In 1951 Lasswell proposed that “policy scientists” should conduct research that was directly and immediately useful to decision makers, while employing “appropriate” quantitative methodologies that acknowledged the limits of data availability and the pressures of time and scarce resources in the decision-making process. Key is best known for his work on political parties, interest groups, electoral behavior, and public opinion. Although he disagreed with the behavioralists’ fundamental tenets, he pioneered many of the statistical techniques and analytic concepts later employed by them.

**THE BEHAVIORAL REVOLUTION**

The positivist influence reached its apogee in the “behavioral revolution” of 1950s, which consolidated the discipline’s paradigm shift, first, by codifying behavioral methodology and, second, by finally rejecting outright the concept of the state. The behavioralists broke with the earlier practice of political scientists by claiming to have discovered a “value-neutral” science and by viewing all earlier works on politics as merely a storehouse of hypotheses for
empirical falsification or verification. This attitude toward political philosophy widened the long simmering rift between empirical political science and normative political theory with the latter regarded as an “unscientific” legacy of the discipline’s past.

Behavioralism’s main methodological claim was that uniformities in political behavior could be discovered and expressed as generalizations, but that such generalizations must be testable by reference to observable political behaviors, such as voting, public opinion, or decision making. Most behavioralists equated observation with quantification to a degree that went beyond what Merriam, Key, or Laswell had considered “appropriate quantification.” Finally, the behavioralists proposed a “pure science” where the theoretical explanation of political behavior was to precede the solution of urgent practical policy problems in society.

The concept of the state, which had been central to political science, was also displaced in the 1950s by a concept of the “political system” that is mainly associated with Talcott Parsons’s systems analysis. Parsons’s sociology identified the political system with behaviors and institutions that provide a center of integration for all aspects of the social system. David Easton echoed this view by declaring, “neither the state nor power is a concept that serves to bring together political research” and instead defined the political system as “those interactions through which values are authoritatively allocated for a society” (1953, p. 106). Systems analysis was tied closely to various theories of decision making, but most notably to pluralist theory, which viewed decision making as the outcome of peaceful bargaining between interest groups in society. Easton emphasized that to account for the persistence of political systems, one had to assume that they successfully generate two “system outputs”: (1) the political system must successfully allocate values for a society (decision making); and (2) the political system must induce most members to accept these allocations as binding, at least most of the time (legitimacy). These “policy outputs” feed back into the social, economic, international, and natural systems to generate new inputs and demands that must be continually processed by the political system.

Easton’s model of the political system stimulated a great deal of research over the next two decades on decision making, interest groups, political communications, political parties, elections and voting behavior, legislative behavior, political socialization, political beliefs, and the policy process. These fields of research have also been characterized by ever increasing levels of sophistication in the use of statistical techniques and concepts. However, the systems model was often limited in applicability by its emphasis on system stability and the assumption of institutional arrangements peculiar to Western democracies. These limitations were partly addressed by the functionalists, who employed a modified concept of the political system that focused on “functions” and “processes,” while acknowledging that the same functions could be fulfilled in various political systems through different processes or institutions. Functionalism was particularly influential in the study of comparative politics and non-Western political systems, where there were different institutional arrangements or where the use of statistical techniques was hampered by the absence of data and technology.

During the 1950s the political science discipline also assumed its current form as a collection of distinct subfields with most political scientists specializing in one or two subfields, while having less and less interaction with practitioners in other subfields of the discipline. The standard subfields are American government, comparative politics, international relations, political theory, public administration, and public policy, although the two latter “applied” fields have often been shifted into separate academic units, such as schools of public administration or public policy, while political theory is now actually practiced as often by historians, philosophers, and literary critics as by political scientists.

THE POSTBEHAVIORAL REVOLUTION

Political science entered a postbehavioral revolution amidst the political rebellions of the late 1960s and the new social movements of the 1970s and 1980s. New intellectual currents, such as neo-Marxism, postpositivism, poststructuralism, and postmodernism were conjoined with a variety of political movements, including pacifism, feminism, environmentalism, postcolonialism, and the gay and lesbian liberation movements. Easton identified the source of the postbehavioral revolution as a “deep dissatisfaction with political research and teaching, especially of the kind that is striving to convert the study of politics into a more rigorously scientific discipline modeled on the methodology of the natural sciences” (1969, p. 1051). The behavioral persuasion remains the dominant orientation of the official discipline, but it has been challenged numerous times since the late 1960s.

One of the most significant intellectual challenges to the behavioralist paradigm and to pluralist theory was the return to the state initiated in the late 1960s by Marxists, such as Ralph Miliband and Nicos Poulantzas and then carried forward by the “new institutionalists.” Nicos Poulantzas’s Pouvoir Politique et Classes Sociales (1968), and Ralph Miliband’s The State in Capitalist Society (1969) directly challenged systems analysis and pluralist theory by drawing on a radical tradition identified with the writings of Karl Marx, Friedrich Engels, V. I. Lenin,
and Antonio Gramsci. These authors developed theories of the state that questioned the basic assumptions of the dominant political science, particularly its assumption that political power is distributed more or less equally among different social groups. At the height of his popularity in the mid-1970s, Miliband was recognized as one of the leading political scientists in the English-speaking world, while Nicos Poulantzas was arguably the most influential political theorist in the world for a time.

However, the interest in state theory waned temporarily as many political scientists abandoned the quest for grand theory in the context of a more widespread intellectual disillusionment with grand scale metanarratives, such as state theory and their attendant transformational political projects. The shift from Marxist to post-Marxist to poststructuralist and postmodernist theory shifted the analysis of power from macroscopic to microscopic forms of power and, therefore, to the multiple “technologies of power” such as language, family, interpersonal relationships, culture, leisure and entertainment, and the configurations of repressed desire (Foucault 1972, p. 12).

The growing discontent among a minority of political scientists led to the establishment of the Caucus for a New Political Science in 1967. The Caucus includes political scientists of many diverse viewpoints, but it is united by the idea that the discipline should abandon “the myth of a value-free science” and advance a progressive political agenda. While originally founded as an alternative to the APSA, it won recognition as the first organized section of the APSA with the right to sponsor its own panels, collect dues, and to publish its own journal New Political Science. Members of the Caucus have authored numerous commentaries on “the tragedy” of political science, “the crisis” in political science, and “the flight from reality in political science.” In 2000, these discontents again resurfaced in the “perestroika” rebellion, which denounced the APSA as an organization controlled by “East Coast Brahmins,” which promotes a “narrow parochialism and methodological bias toward the quantitative, behavioral, rational choice, statistical, and formal modeling approaches” (Monroe 2005, pp. 1, 9).

While Caucus members remain a small proportion of the APSA’s membership, it established a precedent that has resulted in the proliferation of “organized sections” to represent the interests of political scientists in interdisciplinary, subfield, and methodological research outside the official discipline. There are now 37 organized sections in the APSA, whose combined membership is greater than that of the discipline as a whole and attendance at “section” panels of the APSA’s annual meeting tends to be higher than at the “disciplinary” panels. Political science is now fragmented into so many subfields, methodological approaches, area specializations, and theories that “political scientists apparently come together at APSA meetings, but only in spatial terms” (Yanow 2003, p. 398). The future of the discipline in the next century is not clear, but its development over the last century has been characterized by the accretion of multiple approaches. Despite major paradigm shifts, no conception of the discipline is ever completely displaced by another approach and the discipline is now clearly marked by a lack of consensus concerning its basic concepts, theories, and methodology.

**POLITICAL SCIENCE, BEHAVIORAL**

Behavioral political science is an approach to the study of politics that claims to be more “scientific” and methodologically sophisticated than the older, so-called “traditional” political science. Although the study of politics and government dates back to Plato and Aristotle, Greek philosophers in the fourth century BCE, political science only emerged as a separate academic discipline toward the end of the nineteenth century. Since that time, the science of politics has shifted from a descriptive focus on political history, formal institutions, and legal codes to a more “behavioral” emphasis upon decision-making processes, the political behavior of individuals and groups, and their informal relationships. Methodologically, behavioral political science has replaced the predominantly historical, legalistic, and institutional studies of the traditional approach with the more empirical methods of modern social science, borrowed mostly from the field of psychology.

Broadly defined, the traditional approach of political science was concerned with the purpose, nature, and organization of the “state,” stressing humanistic, ethical, and philosophical perspectives. The traditionalists shared a preference for intensive case studies and other qualitative observations in which inferences were derived on the basis of subjective norms and values. Quantitative methods were only rarely used, because the traditionalists doubted that the “scientific method” of the natural sciences could be successfully applied to the investigation of the more indeterminate human behavior. Research typically focused on the detailed description of historical data, political institutions, constitutions, and legal systems, earning traditionalists the label of “hyperfactualists.”

Traditionalist political scientists regarded both empirical and normative questions as equally worthy of scholarly attention, often undertaking their studies because of strongly held personal opinions about the nature of politics. Many of their inquiries showed a normative or prescriptive slant, trying to describe the general principles and best-suited institutions of “good” government. They were also inclined to examine the influence of human values in politics and prescribe specific public policies.

In contrast, behavioral political science has attempted to apply the methodologies of empirical natural sciences to the study of politics and government. In response to the influential political scientist Heinz Eulau’s (1915–2004) call for political scientists to study behavior, not institutions, the field has focused analysis on the political behavior of individuals and groups, rather than on their formal roles or the structures within which they function. Although little consensus exists about the exact characteristics of the so-called “behavioral revolution” in political science, the scientific method of the behavioralists emphasizes the collection of observable data and the use of statistical analysis based on many recorded cases. Behavioral political science claims to be “value-neutral” in the sense of separating fact from value and describing political phenomena without judging their goodness or morality.

Behavioralist-oriented political scientists try to be more rigorous and disciplined in their research, seeking scientific precision by the quantification and measurement of collected data. Through the formulation and systematic testing of empirical hypotheses, they attempt to...
discover regularities and uniformities in political behavior, which can be expressed in generalizations or theory. Behavioralists see a close relationship between theory and empirical research in the sense that theory should be “verifiable” by analysis of observed behavior, while the process of seeking and interpreting empirical data should be guided by theory. Behavioral political science is concerned with the cumulative acquisition of law-like generalizations about human behavior and suggests a close relationship with the other social sciences.

The “behavioral revolution” in the science of politics emerged as a major force in the 1950s and won over much of the field during the 1960s. For years its supporters and detractors debated whether or not behavioralism represented a Kuhnian “scientific revolution,” producing a “paradigm shift” in the basic values and objectives concerning the nature of political science and how the pursuit of systematized knowledge about politics should be conducted. According to Thomas Kuhn (1922–1996), one of the most famous philosophers of science, a scientific revolution is a noncumulative revolutionary development in which an older scientific (paradigm) is supplanted by an entirely new, incompatible tradition that does not build on preceding knowledge. As the behavioralist approach gradually established itself, a new emphasis on methodology and the use of quantitative tools of analysis swept the field and increasingly became the preferred instrument of research, as reflected in refereed academic journals, scholarly books, and professional conferences. The behavioralist approach has made some remarkable contributions to the discipline, especially in providing political theory with a strong empirical basis and in dissecting the “social bases” of politics, as well as in examining comparatively the “political culture” of average citizens, as in the classic study by Gabriel Almond and Sydney Verba, The Civic Culture: Political Attitudes and Democracy in Five Nations.

By the late 1960s, however, the behavioral mode of inquiry came under heavy attack for its preoccupation with methodology at the expense of substance and public-policy orientation. Many younger political scientists criticized the distinction between fact and value, or “value-free” science, as abstract, sterile, and irrelevant in the age of the Vietnam War and the Watergate scandal. Far from being value-free and scientific, behavioralism was seen as static, pro-status quo, imbued with conservative values, ethnocentric, and presenting a highly idealized model of American politics. Behavioral political scientists were accused of focusing on trivial subjects of inquiry (such as analyzing accumulated statistics from elections, public-opinion surveys, legislative votes, and other easily quantifiable data), while ignoring the great ideological struggles of the day. The new movement, which the renowned Canadian-born political scientist David Easton called the “postbehavioral revolution,” reaffirmed the obligation of political scientists to be more problem-oriented and concerned with class relations and conflict, as well as to use their expertise about politics to improve public life. Postbehavioralists wanted to reverse some of the “excesses” of the behavioral school by placing substance before technique, policy orientation before ahistorical “pure science,” and the service of society before academic neutrality and moral relativism.

While the fundamental changes wrought in political science by the behavioralist emphasis on empirical theory and quantitative methods now seem irreversible, what emerged from the postbehavioralist revolt of the early 1970s was a widespread recognition that practical relevance and ethical evaluation of politics are equally important. The discipline has since moved to a “postbehavioral synthesis” of the traditional and behavioralist approaches, combining the empirical perspectives and statistical tools of behavioralism with renewed concern for change-oriented values and the use of specialized political knowledge to solve societal problems.

POLITICAL STRATIFICATION
SEE Stratification, Political.

POLITICAL SYSTEM
Political system refers broadly to the process by which laws are made and public resources allocated in a society, and
to the relationships among those involved in making these decisions. The term, however, has acquired not only a descriptive meaning but also a methodological one. In the first case, “political system” describes how the institutions of a government function together to translate the desires, or “preferences,” of a society’s citizens into laws governing that society. Descriptions of the political system of the United States, for example, focus on how the Congress (House and Senate), the executive (the president and the bureaucracy), and the judiciary (the Supreme Court and lower courts) collectively make, implement, and enforce public policy. They also tend to describe how citizens make their preferences known to members of these institutions through voting and interest-group advocacy and how citizens respond to the policies actually produced. Though undergraduate textbooks often claim to use a political systems approach in their organization, in practice they tend to describe the structure and behavior of citizens and institutions in relative isolation from each other. By contrast, a true systems approach would emphasize process, or how these institutions function together and how their relationships and the policies they produce change (or fail to change) as the preferences of citizens change.

Political systems, however, need not conform to the American descriptive model. Other systems may receive citizen input in different manners or process it into policies through different institutions and relationships. The British political system, for example, is perhaps a simpler system because it does not possess separate legislative and executive institutions (the prime minister is also the majority party leader in Parliament). Political systems in other nations may listen only to the preferences of a few privileged citizens. Perhaps the most degenerate political system is the dictatorship, where preferences and lawmakers are vested in only a single individual.

Political system as a methodological concept grew out of efforts to scientifically study politics and predict political behavior using the “systems approach,” an intellectual movement arising late in the first half of the twentieth century advocating the application of physical and biological systems models to the study of human behavior (Hammond 2003). In the wake of Talcott Parsons’s (1951) argument that society is best understood as layers of systems, several leaders of the Behavioral Revolution, most notably David Easton (1965, 1981), advocated a systems approach to studying the processes of lawmaking and the function of institutions. Broadly speaking, the approach required researchers to differentiate the system from its larger social environment, identify its key components (institutions) and the relationships binding them together, learn how citizen preferences were communicated to them, and identify the “homeostatic” mechanisms that kept the resulting policy outputs stable and the system in equilibrium when these inputs remained constant. More importantly, systems analysts were concerned with whether and how policy outputs would change as different social groups mobilized and articulated new demands on government and how great the difference between these inputs and policy outputs, the feedback loops, would have to be to stimulate resistance and even revolution. Classifying states by different systems was even promoted by Gabriel Almond (1956) as the key to comparative political research.

Political systems theory was largely abandoned as an overarching methodology for a couple of reasons. On one hand, opponents of empiricism in political science criticized it for its focus on steady-state equilibria and search for generalizable behavior over the study of the unique, as well as its emphasis on quantification and hypothesis testing (Wilson 1961). On the other hand, proponents of empirical analysis also found its use as a unifying methodology to be cumbersome and overreaching. Difficulties in identifying the system’s boundaries, testing the functions of individual institutions and their interaction with each other as hypotheses, and measuring concepts such as feedback loops with the linear analysis methods commonly employed proved too intractable. Instead, political science has adopted a more reductionist approach by studying the political system’s pieces, meaning various institutions, interest groups, and voters, in relative isolation. Although the last decade has seen some renewed interest in linking these pieces, political science is still a long way from returning to the political system as a unified theory.

POLITICAL THEORY

Political theory lies at the intersection of the contemporary disciplines of philosophy and political science. Among philosophers, political philosophy is often distinguished by its preoccupation with practical matters. Among political scientists, political theory is often understood as the least practically relevant of the major subfields. In truth, self-identified political theorists are engaged in a wide range of activities, both normative and empirical, scientific and spiritual, esoteric and practical. In addition, the history of political thought encompasses many people who would not necessarily understand themselves to be primarily political thinkers or philosophers (e.g., Julius Nyerere, Sophocles, and the Buddha).

The meanings and purposes of political theory are contested within the academic discipline because a great deal of political theory involves thinking about the nature of politics itself. Therefore, rather than describing what political theory is, it is more appropriate to describe what it has been concerned with thus far, with the understanding that the contours of the history of political thought are also part and parcel of the discussion of what constitutes “politics.”

In general, political theory attempts to understand and form the human character, with particular emphasis on how people coordinate their ways of life, aims, needs and desires, and their potential to act together as a collective. One of the most important insights of political philosophy is the notion that human beings have the capacity to explore, imagine, and implement associations configured in various ways. Across cultures and throughout recorded history, at least three important and interrelated themes recur in such configurations:

1. **Femininity and masculinity.** Notions of gender often divide labor, determine the distribution of goods, and create and order the public and private spheres.

2. **The spiritual and material worlds.** Understandings of the interplay between God or gods and human beings, along with the idea that the spiritual world does not exist, often shape the nature of authority and rule.

3. **Human beings and the environment.** Ideas about the place of human beings in the natural world, and the idea that people can be distinguished from it, typically undergird various political orientations.

As these themes suggest, political theory often intersects with philosophical perspectives in sociology, economics, ethics, and theology. However, political theory lays special claim to understanding and developing ideas about formal and informal rules of collective action and interaction, such as when and how decisions are made, who can and cannot speak, and what kinds of actions are required, sanctioned, or prohibited. This interest in institutions involves the study and development of certain concepts, including justice, power, consent, citizenship, duty, legitimacy, sovereignty, freedom, equality, punishment, property, oppression, rights, liberation, and deliberation. In the last two centuries, approaches to these concepts have often been framed in terms of ideologies, including nationalism, fascism, authoritarianism, democracy, theocracy, communism, secularism, socialism, liberalism, Islamism, republicanism, colonialism, and postcolonialism.

Such concepts form the parameters of governance and law, habits and customs, appropriateness, and virtue in a wide variety of groupings. Such groupings are themselves the subject and creation of political thought and include families, extended kinship relations, castes, factions, interest groups, tribes, parties, communities, cities, classes, ethnicities, nations, races, confederations, states, genders, caliphates, dynasties, empires, colonies, international organizations, and the relations between these entities. Indeed, the idea of “humanity” itself is a primary subject, and some would argue a creation of, political thought. Deconstructing and reconfiguring such arrangements is also an important task of political theory.

Political theorists often posit new ideas through the resuscitation and reinterpretation of old ideas, frequently by analyzing the thought of a particular thinker or thinkers. Examples include: Socrates, Plato, Aristotle, and the Stoics, in the ancient Greek tradition; al-Kindi, al-Farabi, Avicenna, and Sohravardi, in the Islamic tradition; Saint Augustine, Nyerere, Nkrumah, and Sékou Touré in the African tradition; Confucius, Mencius, Mo-tzu, Chuang-tzu, Han Fei-tzu, and numerous thinkers influenced by Taoism and Buddhism in the Chinese tradition; Aquinas, Machiavelli, Hobbes, Montesquieu, Wollstonecraft, Marx, and Mill in the European tradition; Bartolomé de las Casas, Jefferson, Madison, Bolivar, and José Marti, in the American tradition; and the Vedas, written by many seers, as well as the Buddha (Siddhartha Gautama) and Mahatma Gandhi, in the Indian tradition. A full accounting of influential contemporary political thinkers would include hundreds of names from various philosophical schools and political movements (e.g., existentialism, feminism, the Frankfurt school, postcolonial studies, and environmental philosophy). Listing individual thinkers also raises questions about the proper conduct of political theory and, in particular, its relationship to political action by necessarily excluding the oral traditions of many cultures both living and dead.

POLITICS

The term politics derives from the ancient Greek word polis, meaning “city-state,” the main form of political community in ancient Greece. We continue to use the term even though few city-states remain in existence. A commonsense understanding of the term is illustrated by this analogy: Politics is to the polis what athletics is to athletes. Just as the world of athletics is subdivided into different types of sport, politics comes in numerous modes and orders: democratic, tyrannical, constitutionalist, oligarchic, theocratic, bureaucratic, fascist, authoritarian, and so on.

However, everyday language is not a reliable guide to defining politics, because we regularly apply the term to practices that are not political. We speak of office politics, locker-room politics, or the politics of high school cliques. These usages are too broad and fail to distinguish politics as a unique activity, distinct from business, sports, social interactions, and so on. In order to gain a more comprehensively scientific understanding of the meaning of politics, it is helpful to consider two basic components: (1) the character of political activity and (2) the scope of political activity.

THE CHARACTER OF POLITICAL ACTIVITY

Politics has been defined in numerous ways. The philosopher Plato (c. 428–348 BCE) defined it as the art of caring for souls, meaning that the duty of political rulers is to cultivate moral virtue or excellence in their citizens. Numerous thinkers throughout history have reiterated Plato’s view. The medieval theologian Saint Thomas Aquinas (c. 1224–1274), who closely studied the philosophy of Plato’s student Aristotle (384–322 BCE), characterized politics as the activity of bringing together diverse individuals and groups, including doctors, economists, professors, and priests, each with their own talents and characteristics, into a unity: “The object for which a community is gathered is to live a virtuous life. For men to consort together that they may thus attain a fullness of life which would not be possible to each living singly: and the full life is one which is lived according to virtue” (Fuller 2000, p. 85). Both Plato and Aquinas were concerned with cultivating virtue and living a good life. Aquinas further emphasizes the synthetic or “architectonic” dimension of politics as the activity of building coalitions and maintaining harmony among the constituent parts of political society. Politics for Plato and Aquinas reflects humanity’s sociable nature.

Ancient and medieval thinkers emphasized the moral purpose of politics (the why) and the means of reaching that purpose (the how), while modern thinkers, including contemporary political scientists, are more likely to emphasize only means (the how). For example, the Renaissance thinker Niccolò Machiavelli (1469–1527) wrote in The Prince that it is unrealistic for princes to provide moral guidance to citizens because politics requires rulers to perform unjust deeds to ensure the security and glory of the state, including such acts as treating one’s friends as subjects and killing family members if necessary. Machiavelli thus introduced what would later become known as the fact-value distinction into the study of politics. It states that facts are the only objects that can be analyzed empirically and with certainty, while values are less certain. Thomas Hobbes (1588–1679) provided what in the early twenty-first century one would consider a more scientific understanding of politics. His method was to deduce political principles from general and abstract theories. In his view humans resembled atoms, and human behavior was “matter in motion,” whose principle mode of behavior was self-preservation. Unlike Plato and Aquinas, Hobbes regarded humans not as social but as asocial. He sums this up in his famous formulation of human behavior:

So that in the first place, I put for a general inclination of all mankind, a perpetual and restless desire of power after power that ceaseth only in death. And the cause of this is not always that a man hopes for a more intensive delight than he has already attained to, or that he cannot be content with a moderate power, but because he cannot assure the power and means to live well, which he hath present, without the acquisition of more. (Hobbes 1996, p. 70)

This general principle of human behavior leads Hobbes to characterize the activity of politics as the pursuit of peace and security, not as the perfection of human social inclinations. While Hobbes was not what in the early twenty-first century one would call a liberal democrat, his theory laid the foundations for liberal democracy by making consent the basis of government. He also placed politics on a lower (and in his eyes, more stable) ground than earlier thinkers by making peace and security its purpose, not the cultivation of virtue and community.
Machiavelli and Hobbes’s distinction between the moral purpose of politics and the pragmatic pursuit of power can be seen in some twentieth-century definitions of politics, which de-emphasize moral excellence in favor of the use of power and the distribution of goods within a community. The French thinker Bertrand de Jouvenel (1903–1987) defined politics as the activity of gathering and maintaining support for human projects: “We should regard as ‘political’ every systematic effort, performed at any place in the social field, to move other men in pursuit of some design cherished by the mover” (Jouvenel 1963, p. 30). Allan Ball emphasizes conflict in his definition: “[Politics] involves disagreements and the reconciliation of those disagreements, and therefore can occur at any level. Two children in a nursery with one toy which they both want at the same time present a political situation” (Ball 1971, p. 20). Harold Lasswell emphasizes distribution in his treatment of politics, as reflected in the title of his 1936 treatise Politics: Who Gets What, When, and How.

While these definitions have their benefits, they fail to distinguish political activity from other forms of activity. This is especially true for Ball’s definition, which provides little guidance on the difference between a nursery and a nation-state like the United States. More promising is Bernard Crick’s definition of politics as “the activity by which different interests within a given unit of rule are conciliated by giving them a share in power in proportion to their importance to the welfare and the survival of the whole community” (Crick 1972, p. 22). This definition recalls Aquinas’s characterization of politics as unifying different parts of society. By mentioning survival, Crick also alludes to the fact that a political society requires a large degree of autonomy, in a way that a smaller unit, such as a family, lacks. By mentioning welfare, which is broader than survival, he also indicates that a political society is organized around a set of goals and principles.

THE SCOPE OF POLITICAL ACTIVITY

The activity of politics, then, consists of a continuous attempt to fashion a unity from a diverse set of competing interests and talents. Beyond this, any analysis of politics needs to move to a more concrete level. Politics, as the activity of the polis, depends on the form the political community takes. Political actions such as the conciliation of interests would take different forms in Nazi Germany, for example, and a liberal democracy like the United States. In the former, power is based on a personality cult surrounding Adolf Hitler for the purpose of furthering the utopian ideal of a Third Reich. In the latter, coalitions of interests form and compete with one another in a law-based constitutional system. In the former, politics is seen as something that will in fact cease once the utopia is reached (this is true of any utopian system). In the latter, politics is assumed to be a never-ending activity of negotiation and bargaining, on the assumption that a diversity of opinions and interests will always exist.

Political thinkers have devised a variety of methods for evaluating the differences among political systems. Plato distinguished five regimes, ranked according to the degree to which each is just. In descending order, they are the just city governed by philosopher kings, timocracy (ruled by warriors), oligarchy (ruled by the wealthy), democracy (ruled by the many), and tyranny (Plato 1991, pp. 449a–592b). Aristotle distinguished six different regimes according to who rules and for what purpose. He identified three good and three corrupt systems: (1) monarchy and tyranny, (2) aristocracy and oligarchy, (3) polity, or constitutional democracy, and mass democracy (Aristotle 1984, pp. 1288b10–1296b15).

Plato and Aristotle’s typologies are based on the polis. Modern scholars have developed typologies that attempt to organize the different forms the modern state takes. Three separate axes can be identified: (1) the interpenetration of state and society, (2) whether the state is presidential or parliamentary, and (3) whether the state is federal or unitary (Dickerson and Flanagan 1998, pp. 209–310; Finer 1999, pp. 1473–1484).

The first axis considers the extent to which state institutions and civil society are autonomous. For example, liberal democracies prize pluralism, which requires a multiplicity of political parties competing for power as well as a wide array of independent schools, newspapers, and other sources of opinion. Totalitarian governments—for example, that of Hitler—attempt to control all facets of society, including universities, newspapers, unions, and businesses. Totalitarian states permit only one party, which purportedly speaks for the nation.

The second axis considers the composition of the representative institutions. In a presidential system like the United States, the central government is divided into three branches: executive (the president), legislative (Congress), and judicial (the Supreme Court). These three branches balance one another to ensure that no single branch of government possesses complete power. In a parliamentary system like that of Great Britain, executive power (the prime minister and cabinet) is more fused with legislative (the House of Commons). According to the doctrine of responsible government, the prime minister and cabinet must continually maintain the confidence of the House of Commons, which has the power to dissolve the government. Dissolution can occur at any time, in contrast to the U.S. presidential system, where members can only be removed by election or, in extreme circumstances, by impeachment.
The third axis reflects the territorial size of a society. In ancient Greece the polis was not divided into states or provinces because city-states were small enough for government to exert control over its territory and maintain solidarity among its citizens. Modern nation-states are considerably larger in size, which poses special challenges for controlling territory and promoting social solidarity. A federal state splits up the nation-state into states or provinces and hands over to those small units specific powers appropriate to them while maintaining the powers necessary to address national concerns. Large nations such as the United States and Canada have a federal system, while smaller nations such as Great Britain are unitary. Federal systems are based on the view that citizens will have greater solidarity with those who live nearby and who share common ways of life, though this view is less salient when a society has a highly mobile population.

THE STUDY OF POLITICS

The political analysis of major thinkers like Plato, Aristotle, Machiavelli, and Hobbes attempted to combine the empirical study of politics with normative concerns, though the latter two dissolve that combination somewhat. Politics is studied in the early twenty-first century at the academic level in departments of political science. While the term political science is a translation of Aristotle’s politike episteme, modern usage, with the emphasis on “science,” reflects the attempt, begun by Hobbes, to study politics according to the methodologies of the physical sciences.

The division of most departments of political science into four subfields of analysis reflect this methodology. Political philosophy, which focuses on normative questions of political life, is one subfield. International relations considers the complexities of the international order, including law, organizations, war, and political economy. Comparative politics examines the politics of various countries and regions of the world. A fourth subfield examines the politics of the native country, so, for instance, every political science department in the United States has an American politics subfield, and their counterparts in Canada have Canadian politics subfields.

Political scientists frequently step outside of their subfields. This is most true of political philosophy and its relation to other fields, as few political phenomena can be separated from their normative dimensions. For instance, the study of power requires one to consider why a political actor seeks power, and these reasons usually depend on that actor’s particular understanding of justice. As a result, political science involves the study of the good society, just as it did for Plato 2,500 years ago.

POLITICS, ASIAN AMERICAN

Americans of Asian heritage have been one of the fastest growing population groups in the United States over the last several decades. According to the U.S. Census Bureau, there were fewer than one million U.S. residents in 1960 who identified themselves as Asian, or less than 0.5 percent of the total population (“Asian” here refers to Americans with a Far Eastern, Southeast Asian, or subcontinent Indian background). By July 2004, this number grew to 14 million, or roughly 5 percent of the total U.S. population (based on individuals who identify as “Asian alone or in combination” with other racial groups, according to the current census classification system). This trend
is expected to continue, with current census projections of 33.4 million Asians in America by midcentury. This population, moreover, is highly concentrated in particular states and cities in America. For example, Asian Americans make up 58 percent of Hawai'i’s population and 12 percent of California’s population. Asian Americans also make up 68 percent of Honolulu’s population, 33 percent of San Francisco’s population, and, in the two largest “gateway” cities, 11 percent of the population of both New York and Los Angeles.

Many observers of this demographic growth predict that Asian Americans will soon be a rising political force in the United States. Several Asian Americans have already ascended to prominent elected and appointed offices, including former Democratic governor of Washington Gary Locke, Democratic senators Daniel Akaka and Daniel Inouye (both from Hawaii), members of Congress Bobby Jindal (R-LA), Mike Honda (D-CA), Doris Matsui (D-CA), and David Wu (D-OR), and Bush Administration appointees Elaine Chao (U.S. Secretary of Labor) and Norman Mineta (U.S. Secretary of Transportation). At the same time, Asian Americans in elected and appointed office are conspicuously underrepresented relative to their numbers in the general population.

More importantly, a group’s political fortunes often depend critically on the number of its members who vote and the number of those votes that can be delivered to a particular political party. In this instance, the power of Asian American electorate is far less clear. Based on 2004 data from the Current Population Survey, only 69 percent of Asian Americans are eligible to vote (as citizens), 36 percent are registered to vote, and only 31 percent report having voted in the last election. The proportions in the general population, by comparison, are 91 percent citizens, 66 percent registered to vote, and 58 percent reported voting. Much attention has thus turned to the question of why Asian Americans “underparticipate.” The most commonly mentioned answer is that Asian Americans are simply less interested in politics and less invested in their long-term future in the United States. This view, while perhaps true in isolated instances, gives an incomplete portrayal that almost certainly evokes insidious stereotypes of Asian Americans as inscrutable, insular, and perpetually foreigners.

Roughly two of every three Asians in the United States are foreign born. As such, factors specific to the immigrant experiences and institutional inclusion of Asian Americans better explain their (under)participation. For one thing, Asian American political participation generally rises with one’s immigrant generation and length of stay in the United States. Furthermore, contrary to the perceived wisdom, the availability of dual nationality does not divide the loyalties of Asian Americans or diminish their political engagement; if anything, Asians in the United States who come from countries allowing for dual nationality are more likely to be U.S. citizens and to vote than their counterparts from countries that make no such allowances. A third important factor is language. In particular, the availability of language assistance or multilingual ballots is key to the participation of many Asians in the United States.

As for mediating institutions, the mobilization of voters by political parties has been and still remains a decisive factor. Whereas parties in the era of urban “political machines” played a central role in the political mobilization of immigrants from European shores, parties in the mid-2000s were strong as national organizations but much weaker as local institutions that bring new Americans into their partisan fold. In their place, civic associations such as places of worship, unions, ethnic organizations, and community-based organizations were increasingly central as institutional forces that mobilize Asian American communities.

The relative absence of political parties as mobilizing institutions is also often reinforced by the prevailing belief that Asian Americans do not cast their collective political fates behind a political party. This belief is true in the sense that a plurality of Asian Americans, when given a choice, opt to affiliate with neither the Democratic nor the Republican Party. But it is untrue (and increasingly emphatically so) that Asian Americans have no preferences between the Democratic and Republican parties. In the 2004 presidential election, an exit poll conducted by the Asian American Legal Defense and Education Fund found 74 percent of its Asian American respondents who reported voting for John Kerry; 57 percent of poll respondents identified themselves as Democrats, compared to only 15 percent who identified as Republicans and 26 percent who did not affiliate with a party.

A final important consideration is that the political interests and identities of Asian Americans remain relatively ambiguous and amorphous by comparison, say, to that of African Americans. Only a small proportion of Asians express a strong sense of panethnic solidarity as “Asian Americans,” exhibiting instead far stronger ties to ethnicity or national origin (i.e., as Japanese, Korean, Vietnamese, Pakistani, Taiwanese, and so on). This is the result in part of Census Bureau classifications that bring together a dizzying phenotypic, national, linguistic, religious, and ideological, inter alia, diversity of peoples under the common rubric of “Asian American.” It is also the result in part of the mythical status of Asian Americans as “model minorities”—hard-working, law-abiding, family-oriented, education-revering people who embody the virtues of the American Dream. This model minority myth essentializes and homogenizes the diversity
of Asian American experiences. It functions ideologically to reproduce racial hierarchy in the United States by exaggerating the prosperity of Asian Americans while continuing to cast them as "perpetual foreigners" and exploiting the hard-earned gains of Asian Americans as a foil to denigrate the lesser fortunes of African Americans and Latinos.

At the same time, there have been moments of successful panethnic collective action. In the Vincent Chin case in 1982, two white autoworkers in Detroit who clubbed the Chinese American to death while calling him a "Jap" were acquitted of any crime. In the Wen Ho Lee case in 1999, a naturalized U.S. citizen from Taiwan was wrongfully accused of sharing nuclear secrets with the mainland Chinese government. These were two notable instances of "reactive identity formation" that drew a national outcry of protest from Asian Americans. Perhaps the most sustained case here was the decades-long legal challenge and political campaign for "redress and reparations" for the nearly 120,000 Japanese Americans who were forcibly removed from their homes and sent to internment camps during World War II. These efforts contributed to the passage into law of the Civil Rights Act of 1988, which provided $20,000 to each surviving internee and led to the issuance of a formal apology from President George H. W. Bush. It is important, then, to remember that panethnic categories such as "Asian American" are political and social constructions that respond to a collective memory and contemporary experiences of exclusion and racialization—from the 1882 Chinese Exclusion Act and the 1907 "Gentlemen's Agreement" between the United States and Japan to the U.S.A. Patriot Act and the post–9/11 debates over restrictionist immigration policies.

POLITICS, BLACK

Black politics refers to the collective struggle of people of African descent to gain power and influence in the processes and institutions of government as a way of securing and protecting a diverse array of interests that allow them to attain and maintain the rights afforded them as American citizens. It includes not only the actions of black people to assure these rights but also those of other individuals and collective groups with whom these interests and outcomes are negotiated. Research throughout various disciplines of the social sciences have sought to understand the conditions in which black politics have emerged, as well as the wide array of problems, challenges, successes, and failures that have resulted from its pursuits.

HISTORY

Insofar as it is at its core a struggle for and negotiation of power, black politics was initiated within the American institution of slavery. Though dictated for them by both law and custom, African slaves’ identity, status, and relationship to America’s white citizenry represented the beginnings of blacks’ struggle for recognition, power, and legitimacy within the confines of plantation life. While there was no real sense of slaves’ involvement in the formal governments of the nation, slavery was a system in which blacks, though stripped of power generally, nevertheless used means available to them (religious gatherings, informal and secret attempts to educate themselves, underground escape from plantation life, insurrection, and even forging relationships with their white slave masters) to achieve their first steps toward a more perfect real-
ization of a good life—freedom, and recognition as full and equal citizens of America.

However, blacks found that the freedom granted in law by Abraham Lincoln's Emancipation Proclamation did little to guarantee their equal status as full citizens. The years immediately following emancipation were years of uncertainty regarding the status of blacks, particularly in the South—years in which black codes extended the same system of subjugation blacks experienced throughout slavery. Yet soon, the project of Reconstruction, with its Congress-led protections and opportunities for blacks, would show signs for hope and optimism. W. E. B. Du Bois characterized blacks' political struggle for equality during this period (1867–1877) as the "mystic years"; blacks seemed to be on the fast track toward equality. Newly instituted policies such as the creation of the Freedmen's Bureau in 1865–1866, the passage of the Civil Rights Act in 1866 and the Fourteenth Amendment the same year and ratified in 1868, and others granted legal protections and opportunities for blacks to participate in American life. Blacks were afforded educational opportunities through public schools, some of which were integrated. Perhaps the greatest opportunity for blacks to forge their own political destinies was the granting of the right to vote by the Fifteenth Amendment, ratified in 1870 (giving them the ability to determine election outcomes) and the inclusion of blacks in state and federal elected office, including the 1870 election of both Hiram Revels as America’s first black senator and Joseph H. Rainey as the first African American to serve in the U.S. House of Representatives.

However, the promises of Reconstruction would prove hollow after a few short years. White violence against blacks was rampant among such groups as the Ku Klux Klan and in historic riots such as those in New Orleans and Memphis in 1866 or the 1876 Hamburg Massacre in South Carolina. Informal and state-sanctioned barriers to black education and voting became prevalent, black elected officials were either stripped of their power or were made to support policies counter to their interests, and black political and social leaders were cast as buffoons, carpetbaggers, and unscrupulous opportunists in the American imagination, in large part through the white press of the time. By the end of Reconstruction, blacks found themselves stripped of many of the freedoms, opportunities, and means for political engagement they had received a brief taste of in the preceding few years. However, despite the beginnings and persistence of the Jim Crow era in the South that followed Reconstruction, blacks continued to mount considerable political and social influence; through the educational leadership of those such as Booker T. Washington and George Washington Carver, among many others; through the legal profession and such prominent legal figures as Thurgood Marshall and organized legal/political groups such as the National Association for the Advancement of Colored People, founded in 1909; and through the institution of the black press (which had its roots in the pre–Civil War and Reconstruction eras), which spawned more than 500 newspapers between 1880 and 1890.

The 1950s and 1960s ushered a new era of black politics—one born of new struggles and resulting in new political, economic, and social opportunities. Through a variety of “unlawful” channels and struggles engaged in by Martin Luther King Jr. and organizations such as the Congress on Racial Equality (CORE), the Student Nonviolent Coordinating Committee (SNCC), and others, blacks gained much in the 1960s that would lay a foundation for the continued pursuit of black politics. This included landmark legislative initiatives passed in three consecutive years: the Civil Rights bill brought before Congress in 1963, the 1964 Civil Rights Act, and the 1965 Voting Rights Act. Although this legislation opened doors previously closed and locked to black Americans, they did not completely ensure full access to and fulfillment of the rights enshrined on its pages. Yet it was these victories, along with the beginning of a cultural shift in American society to what political scientist Tali Mendelberg refers to as a “norm of racial equality” (2001), that made possible the growth of the idea, movement, symbols, and actions of black political life.

Following these legislative gains, the late 1960s saw a marked increase in the numbers of black representatives in Congress. With the addition of three representatives to the six already seated, the 1970 Congress had the most concurrent black members serving in its ranks. This watershed of black representation led to the eventual formation of the Congressional Black Caucus, which, according to William Clay, “constituted a power-bloc deserving respect within the institution” organized around the idea of a “solidarity of purpose and program [that] would enable the nine of us to wield a significant amount of influence in the House” (1993).

Outside of this official body, a host of other individuals and organizations were working to secure a sense of black solidarity to help ensure that the earlier legislative victories were not hollow. These ranged from “militant” groups such as the Black Panthers, Malcolm X, and the Black Muslim movement to a host of black pride and similar movements that sprang up within the academy. Included were movements to form the first department of Black Studies by sociologist Nathan Hare at San Francisco State University in 1968. Soon, similar departments were begun on college campuses across the country, aimed at understanding the culture and politics of African Americans. Their inauguration would spawn similar departments geared to study the social, political, and cul-
tural life of other American ethnic groups—departments of Latin American Studies, Asian American Studies, and others under the general rubric of ethnic studies. Each of these movements worked in formal and informal ways to secure the idea and trajectory of black politics that developed into a sense of black solidarity and collective action around securing black interests. And although the nature and substance of these interests and means of securing them have changed, the fundamental nature of black politics remains to this day.

**CORE CONCERNS**

There are a number of what might be called “core concerns” related to black politics. Many of these areas of scholarly investigation are related to what is perhaps a single most central concern: equal representation. Despite its presence and protections in civil rights legislation, it is an ideal that many feel has yet to be reached. Social scientists have generally focused their attention on this issue by investigating two broad related areas: the drawing and redrawing of legislative districts in ways that either allow or prohibit the election of blacks to legislative office, and the persistent nature of racial prejudice as it impacts the political process designed to ensure black representation.

Initiated by the Voting Rights Act of 1965, the practice of racially gerrymandering congressional and state legislative districts became a legal way of creating districts with a majority black population, thereby increasing the election hopes of blacks running for political office. Social scientists investigating the effectiveness of such policies have demonstrated strong arguments on both sides of this issue. Scholars who suggest the persistent need for racial redistricting policies focus on a number of research findings: the propensity for white voters to harbor deep-seated prejudices; resentments and fears of blacks; the reality that when primed by racial appeals, whites are likely to be less sympathetic to African American public-policy interests and infer that such would be the case in evaluating black candidates; and that, in general, whites tend to evaluate black political candidates less favorably than their white counterparts. The implication of such studies is that public-policy guidelines such as ensuring “safe” districts for black politicians may be necessary to mitigate the white prejudice that erects a barrier to what political scientists refer to as racial crossover voting.

Scholars whose research suggest that racial gerrymandering is not needed and may even hinder the pursuit of black political interests point to a different set of conclusions: studies of recent elections that demonstrate that white voters are sophisticated enough to sublimate racial attitudes when making voting decisions; research indicating that political ideology and political party affiliation—not negative racial attitudes—are the primary cause for whites’ unwillingness to vote for black candidates; and arguments that suggest that racial redistricting provides for a modicum of “descriptive representation” but does not likely translate into “substantive representation.” This is to say, it ensures that someone who is black will quite likely be elected, but it cannot ensure that the person elected, though black, will necessarily work in the interest of his or her black constituents.

This array of competing conclusions by political scientists, sociologists, and legal and communication scholars writing in the late twentieth and early twenty-first centuries suggests that both the ideal of equal representation for African Americans and the most effective means for securing it are still an open question, persisting as one of the most significant debates within the arena of black politics.

**RECENT TRENDS**

Beyond research surrounding the principal concern of equal representation, much research from the early 1990s to 2006 has demonstrated some interesting trends that have a direct bearing on the present and future state of black politics. These include the shift in policy concerns of African Americans, the growing number of blacks elected to government bodies, and the nature of black participation in the political process.

According to political scientists and communication scholars such as Donald Kinder, Nicholas Valentino, Katherine Tate, Michael Dawson, and others, public opinion on national public-policy concerns continues to be divided between blacks and whites and, increasingly, among blacks themselves. For instance, studies in the early 2000s demonstrated waning—barely a majority—support among blacks for affirmative action policies in hiring practices. Research shows that diminished support from earlier decades has been influenced by gaps among blacks in terms of economic class, levels of in-group identification, and out-group racial resentment. In addition to this, public-opinion surveys conducted around the same time period by the Joint Center for Political and Economic Studies, a think-tank that has researched trends in black politics since the early 1970s, show that although blacks still by and large support policy issues that have long been central interests—social welfare policy, affirmative action, education, and others—few of these concerns rate highly in terms of what blacks say are the issues that most concern them. Thus, it seems that while the public-opinion divide between blacks and whites persists, there is a growing fragmentation of black policy interests and concerns. This has led to a number of related developments, including, but not limited to, waning (although slow) affiliation of blacks with the Democratic Party (always overwhelmingly supported by blacks) and renewed interest in and
strategies by the Republican Party to recruit black political support.

Along with these public-opinion trends, the country has also seen an increase in the number of black elected officials since 1980. While most of these increases have been in state legislative bodies, there has also been a rise in blacks elected to Congress, as well as an increase in the number of black congressional hopefuls running against white opponents (some successfully) in non-majority-black districts. The increased numbers at the state level are likely to translate into continued increases in the numbers elected to higher levels and add to the debate about equal representation and the effectiveness of strategies used to ensure it.

A final area of social science scholarship has paid close attention to trends in black political participation. Research by many scholars in sociology and political science, particularly, has shown that generally the level of African American political participation has steadily declined in the years following the dawn of the civil rights movement. Research has sought to determine the precise causes and consequences of this declining participation. One set of arguments among many supported by the extant literature demonstrates that neighborhood isolation, in conjunction with states of extreme poverty, leads to political isolation—the feeling of being disconnected from the political system and of having no or little political power, which therefore sublimes motivations for political involvement. Other research suggests that a declining sense of black racial group identification has led to decreased interest in black political participation. Much of this research also relates to the increased socioeconomic stratification existing in black communities—a result, to some extent, of affirmative action policies that dramatically increased the size of the black middle class in the 1970s and 1980s.

However, there is much social-scientific evidence to suggest that black political activism and participation in social movements that coalesce around black interests—and increasingly shared interests with other minority groups—is still relatively strong. In this arena, much of the literature has focused on the issue of religious participation, most specifically on the continued relevancy of the black church as a motivating factor for, and conduit of, black political life. The influence of the church has been seen to impact the nature of black political participation in explicitly political activities such as voting and political campaign involvement, as well as less explicit forms of political participation such as volunteerism.

Social science research in the arena of black politics has tackled many significant and controversial issues in more than four decades since the beginning of the civil rights era. While focusing on specific issues and problems, this area of scholarly inquiry has served to create and influence larger discourses about race in America. It has influenced American public opinion as well as the policy-making decisions that have occurred at every level of government that seek to protect the highest ideals of American democracy.

**POLITICS, COMPARATIVE**

Comparative politics designates a distinct subfield in political science. Although Aristotle’s political writings were arguably some of the first works in comparative political inquiry, the field has been most influenced by the writing of nineteenth- and twentieth-century thinkers including Gabriel Almond, Hannah Arendt, Robert Dahl, Harry Eckstein, Samuel Huntington, Seymour Martin Lipset, Karl Marx, and Max Weber. Research in comparative politics seeks to account for the observed variation
over time and among political units on consequential social, political, cultural, and economic outcomes by examining, describing, modeling, and predicting continuity and change resulting from the dynamics among international, national, and subnational actors.

The subfield's methodological orientation is catholic in its use of quantitative and qualitative techniques. Historically, the subfield has emphasized the use of case studies, often employing John Stuart Mill’s methods of difference and similarity, but statistical analysis (mostly on cross-sectional, time-series, and multilevel data), computational methods, and formal modeling have become more prevalent in recent years. Gary King, Robert Keohane, and Sidney Verba (1994) and Henry Brady and David Collier (2004) offer introductions to some recent issues in comparative political methodology.

The field is organized around substantive topics, though disagreement on these canonical elements remains considerable. However, two broad dimensions can be delineated: the statics of political systems and the dynamics of political conflict and cooperation. The study of political systems evolves around the conditions and prerequisites for the establishment and survival of various regime types. Some of the crucial questions include: What distinguishes democracies from nondemocracies and from what lies in between? What explains the successful transition from one political system to another? What is the nature of liberal democracy?

A core debate in the study of democracy is the relationship between wealth and democracy: Some claim that wealth induces democracy, others that wealth simply accompanies democracy but is causally unrelated to it, and still others (e.g., Adam Przeworski) have suggested that wealth sustains democracy once it has taken root. Closely related is the study of democratic institutions and competitive elections, which has focused on the relationship between political institutions and political outcomes, such as collective mobilization, party formation, and policy preferences (e.g., in the work of Gary Cox, Robert Dahl, Richard Katz and Peter Mair, Herbert Kitschelt, and Giovanni Sartori). The study of autocracies has focused largely on developing typologies of authoritarian regimes and on the strategic interaction of elites during the transition to democracies. The comparative study of political liberalism across countries and over time has also received sustained attention in, for example, the work of Ira Katznelson.

Gabriel Almond and Sidney Verba’s *The Civic Culture* (1963) was an early cross-national comparative study of democracy in which the authors linked civic attitudes and democratic stability using a tripartite typology of political cultures—parochial, subject, and participant. The cultures spanned from purely passive to highly engaged attitudes toward the political system and civic life. Almond and Verba argued that political cultures adhere to the principle of congruence between a political structure and the attitudes of its citizens. The study concludes that competent, active citizenries sustain democracies.

The literature on democratization has vacillated between an emphasis on the structural determinants of sustainable democracy and elite incentives and capabilities to modify the political order (Skocpol 1979). The work of Samuel Huntington derives the preconditions for political order both from socioeconomic changes and political institutions. Guillermo O’Donnell and Philippe Schmitter’s work challenges structuralism and represents an actor-centered approach, which argues that the elite split followed by negotiated pacts (which incorporate the preferences of the military) is a necessary precondition for the successful transition from authoritarianism to democracy. Since 1989, the transitions from authoritarian regimes have produced a variety of political outcomes in the gray zone between autocracy and democracy. The study of competitive authoritarianisms (or illiberal democracies) is an emerging field of comparative study.

The study of linkages and distributional conflicts that arise at the intersection between politics, economics, and society has led to the development of an area of inquiry often dubbed “political economy.” The “varieties of capitalism” literature is a prime example (e.g., Hall and Soskice 2001; for discussions of corporatism, see Schmitter 1975). The analysis of advanced capitalist democracies (OECD states) was induced by the oil shocks and the collapse of the Bretton Woods system. Political economy, in the work of Torben Iversen, for example, has since focused on the conditions for growth, stability, wage equality, and redistribution and seeks to untangle the ties between political systems, inequality, and policy formation. One line of inquiry focuses on domestic responses to international challenges, such as global economic competition, trade openness, and international institutions.

The study of dynamics among and within political systems focuses on conflict, revolutions, ethnic tensions, and order in society. The study of revolutions, for example, identifies the sources of state collapse and patterns of group alignment and mobilization. Studies of ethnicity and political culture analyze identity formation and the conditions under which identity is or can be mobilized for political purposes. Comparative politics intersects with international relations in many ways, but most often at the interface of ethnic conflict (e.g., Horowitz [1985] 2000). According to such writers as Donald Horowitz, Arend Lijphart, and David Laitin, the causes and consequences of state failure, intercommunal violence, and the institutional conditions under which ethnically divided
societies can coexist remain core questions in comparative politics.

The third wave of democratization has raised new questions about the relationship between electoral competition and economic reforms and has moved the field closer, in some ways, to international relations in debating the push-and-pull effects of international organizations (e.g., the European Union) or of global economic strategies (e.g., foreign direct investment). New agendas in comparative politics are emerging at the intersection of ethnic-(and culturally) based identities and political mobilization. Topics and subjects developed in the study of the OECD countries are beginning to migrate outside the region to address related issues. Methodologically, the field has benefited from the massive increase in computing power now available to social scientists, but it has not abandoned altogether its reliance on a small number of in-depth case studies. The field appears to be moving recognizably toward the potentially fruitful cross-pollination of quantitative and qualitative research methods and strategies.

POLITICS: GAY, LESBIAN, TRANSGENDER, AND BISEXUAL

The politics of sexual diversity became a subject of scholarly interest soon after a surge in lesbian and gay activism in the late 1960s and early 1970s. Writers publishing in the 1970s and early 1980s on such activism or state response to sexual diversity worked at the margins of publishing and academic disciplines and often outside the academy. In the 1990s, as sexual diversity came to be more publicly recognized, there was a major opening up of publishing opportunities for social science writing on lesbian, gay, bisexual, and transgender issues, though political science was slow to recognize their relevance.

PIONEERING CONTRIBUTIONS

The activism of the 1970s brought visibility to gay liberationist challenges to the gendered foundations and sexual repressiveness of European and North American societies. Gay community magazines and newspapers such as Toronto’s the Body Politic, London’s Gay Left, and Boston’s Gay Community News provided means for nonfiction writers to focus their political visions through a new radical lens. One current of this writing reflected a belief in a clearly demarcated gay and lesbian population with distinctive social and cultural norms. Most writers, however, held that homosexuality was a social and political construct and that only in relatively modern times did it shift from labeling a form of sexual behavior to describing a distinct category of person. The British sociologist Mary McIntosh had articulated such a “constructionist” view in an influential article published in 1968 (“The Homosexual Role”).

The Australian writer Dennis Altman’s Homosexual: Oppression and Liberation (1971) was a liberationist manifesto. Altman was one of the few political scientists to publish on gay issues before the late 1980s, and many years passed before his work was considered a legitimate part of that discipline. In the decade that followed most work on lesbian and gay politics was by historians, sociologists, and independent scholars. One was Jeffrey Weeks’s Coming Out: Homosexual Politics in Britain, from the Nineteenth Century to the Present (1977); another was the U.S. historian John D’Emilio’s Sexual Politics, Sexual Communities: The Making of a Homosexual Minority in the United States, 1940–1970 (1983), which was notable for having been published by an established academic house (University of Chicago Press). Both books pointed to radical questioning of social and political repression in earlier periods, and both adopted “social construction” views by linking the development of homosexual identities to advanced forms of capitalism.

Most lesbian activism was quite separate from gay male activism, and this was soon reflected in published work. Lillian Faderman’s Surpassing the Love of Men: Romantic Friendship and Love between Women from the Renaissance to the Present (1981) was an early example of American writing that sought to claim lesbian visibility. Writers such as Gayle Rubin, Carole Vance, and Estelle Freedman used lesbian feminism as a lens for theorizing the interplay of gender and sexual inequalities and for outlining a distinctive political agenda. At the end of the decade the political theorist Shane Phelan published Identity Politics: Lesbian Feminism and the Limits of Community.

THE IMPACT OF AIDS

The spread of AIDS in the 1980s posed a new threat of stigma but also enhanced the visibility of sexual minorities, reradicalized activism, provoked engagement with state institutions, and created openings to mainstream political processes. It also highlighted issues of workplace discrimination and the formal recognition of the same-sex partners of those who were infected.

This increased intellectual interest in the interdisciplinary analysis of the politics of sexual difference. Altman was one who chronicled the expansion of AIDS activism and the public response to the epidemic from its early stages. A few years later David Kirp and Ronald Bayer produced books on public and bureaucratic responses using more established political science frameworks, and together they edited a collection of essays from several European and North American countries on the politics of AIDS.

It was in the late 1980s that the first comprehensive survey of lesbian, gay, bisexual, and transgender (LGBT) activism was published, The Rise of a Gay and Lesbian Movement by Barry Adam, who like Altman had a comparative vision that extended across and beyond the American and British experiences. This work coincided with a surge of academic interest in social movements, though little of this material was by political scientists and even less of it addressed LGBT activism.

Much of the coverage of the movement in later years emphasized gender divisions or the distinct experience

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
and political agendas of lesbians. Work by Vera Whisman and Becki Ross pointed to widespread fluidity in women’s emotional and sexual experiences and to conscious, politically informed shifts away from men and toward other women. At the same time most accounts noted that wariness of bisexuality was more widespread among lesbians than among gay men, though it was common enough across the gender line to hamper the emergence of bisexual activism for years.

Some of the important analyses of the movements in Britain, Canada, and the United States came from the pens of activists, including Urvashi Vaid, formerly head of the Washington-based National Lesbian and Gay Task Force, and Tom Warner, long involved in the Coalition for Lesbian and Gay Rights in Ontario. Vaid, Adam, and the British sociologist Kenneth Plummer were among those students of the movement who discussed social class inequalities. Most published work on the movement extensively covered divisions within it but focused most often on gender and race or ethnicity more than class.

QUEER THEORY

The early 1990s saw a dramatic growth of publishing on sexual diversity, though legitimacy within the academy was slower to develop. One of the most prominent new bodies of literature was in queer theory, taking up a traditionally derogatory term that had been proudly adopted by young Queer Nation activists at the beginning of the decade. Queer was used in many different ways but usually was intended to indicate a provocative rejection of assimilationist politics and to reflect the wide range of sexual practices and identities rejecting “heteronormativity.”

Writers such as Eve Kosofsky Sedgwick (author of the influential Epistemology of the Closet, 1990), Michael Warner, Judith Butler, and the political theorist Mark Blasius were heavily influenced by the French philosopher Michel Foucault and particularly by the first volume (1978) of his History of Sexuality. They saw “homosexual” and other sexual categories as the products of a regulatory and controlling impulse. Language itself was seen as one of the fields on which power was exercised, though also where resistance was mobilized. Queer theory, like other forms of poststructural analysis, resisted the notion of a universal narrative or a common human experience of sexual difference. Within any particular time and setting too, practices were variable and identities unstable. Not surprisingly writers in such veins often paid particular attention to sexual practices and identities that crossed gender boundaries.

A current of critical legal studies was growing at this time; among the most prolific writers were the British legal scholars Didi Herman and Carl Stychin. The frameworks and very language of law, according to this view, structured the way claims are presented and narrowed the impact of the “victories” gained. Alongside queer theory then, this writing raised critical questions about what was thought to be the assimilationism of mainstream lesbian and gay activism.

DIFFERENCES ACROSS CULTURES AND SOCIETIES

Queer theory’s rejection of universalism dovetailed with discussions of racial and cultural inclusiveness among European and North American activists and the emerging profile of sexual diversity politics in minority communities in European and North American countries and in Asia, Africa, and Latin America (often propelled by AIDS). By the end of the 1990s more writers were taking up questions of cross-cultural and cross-national difference, though not necessarily through a queer theoretical lens. The activist Keith Boykin began writing about African American gay experience, and the political scientist Cathy Cohen then published The Boundaries of Blackness: AIDS and the Breakdown of Black Politics (1999). Both explored the erasure of African Americans in mainstream chronicles of the epidemic and within African American political circles.

At the beginning of the twenty-first century two collections brought together articles on the politics of sexual diversity covering a wide range of countries, one edited by the British activist and political scientist Peter Drucker, the other by Adam and colleagues. This new literature pointed to the influence of Euro-American “identity” models on other regions of the globe but alongside persistent local patterns of sexual practice and self-perception. The best of this writing resisted the temptation to romanticize sexual practices and beliefs about them in pre-colonial non-Western societies and to homogenize the West itself.

THE POLITICS OF RIGHTS

Activist claims for equality secured major gains in the 1990s, propelled partly by the visibility of sexual minorities in an expanding range of countries and partly by the public policy prominence of the issues associated with AIDS. Openly gay candidates for public office were winning elections in the 1980s for the first time, and in the following decade their numbers grew significantly in the United States, Britain, the Netherlands, and other industrialized countries.

In the United States especially, gay and lesbian rights issues became much more prominent as religious conservatives and the Republican Party intensified their opposition to such rights. President Bill Clinton’s 1993 attempt to lift the ban on lesbians and gays serving in the military provoked a firestorm of protest (and some scholarly atten-
A successful court challenge to Hawaii’s marriage law in that same year led to an even greater focus on homosexuality by the Religious Right—a focus sustained for well over a decade. Under George W. Bush’s presidency, the Republican Party was as ready as ever to use the marriage issue to attack Democrats, and a series of state constitutional amendments to bar same-sex marriage was successfully introduced on election ballots in the mid-2000s.

Nevertheless, steady gains were being made in recognizing families led by same-sex couples. As activists in North America and Europe made progress in state systems, writing on their access and impact expanded. Work that deals with legal rights received substantial attention in the United States, which is not surprising given the political importance of litigation. Writers such as David Richards, William Eskridge, Daniel Pinello, William Rubenstein, and Jason Piereson examined the highly uneven record of U.S. courts in terms that provided at least some hope for activists. The influence of critical legal studies is more evident in writings about Canadian law by writers such as Kathleen Lahey, Miriam Smith, Bruce McDougall, Brenda Cossm, and Susan Boyd.

The spread of legal recognition of sexual diversity in Europe has received somewhat less attention but more as issues related to relationship recognition have come to the fore. Robert Wintemute, Kees Waaldijk, and Yuval Merin have chronicled the rapid spread of national regimes of same-sex relationship recognition in the late 1990s and early 2000s as well as the slow march toward equity within European Union institutions.

In the late 1990s and the early 2000s dramatic shifts toward recognizing same-sex relationships (in some cases including marriage) occurred in Canada, Spain, the Netherlands, and several other northern European countries. Most reformed regimes initially excluded or compromised parenting rights for lesbian and gay couples (Canada and Spain being notable exceptions), though greater inclusiveness on that front was slowly spreading in the 2000s.

In no other country has controversy over challenges to family regimes been as sustained as in the United States. Consequently there has been only modest scholarly attention to tracking these changes outside the United States apart from the writings of Waaldijk, Wintemute, and David Rayside.

The enactment of rights measures at the state and regional government levels has received some attention in the United States, where local and state authorities have greater jurisdictional reach in areas related to sexual diversity than in almost any other system. Bob Bailey, Kenneth Wald, Barbara Rienzo, James Button, Steven Haeberle, and Donald Haider-Markel are among the contributors to this field exploring what factors explain rights advances.

Family policy began receiving analytical attention in the United States following the emergence of same-sex marriage as a front-burner political issue during the 1990s and the early 2000s. Writers such as Eskridge and Richards argued for the importance of the issue; others such as Valerie Lehr are more skeptical of the “normalizing” dangers of seeking entry to the traditionally inequitable institution of marriage.

The prioritization of gay-related issues by the U.S. Religious Right eventually produced an analytical literature on that opposition, including work by Wald, Herman, and Clyde Wilcox. As struggles over public recognition intensified, greater analytical attention was paid to public attitudes (for example, by Sherrill). The prominence of the marriage issue in the United States led to a proliferation of analytical treatment on that issue in particular by such writers as Daniel Pinello, William Eskridge, Martin Dupuis, Jonathon Goldberg Hiller, and Andrew Sullivan. Many other issues, such as those related to schooling, policing, and parenting, should have received substantial academic attention but did not.

Transgender politics gets little space in these strands of literature on rights politics. The theorist Paisley Currah is among the few social scientists and is possibly the only political scientist who has written in a sustained way on this topic. Empirical treatments of activist movements or public policy engagement with transgenderism and bisexuality are exceedingly rare, despite the spread of a rhetorical commitment to inclusion.

ACADEMIC LEGITIMACY?

In general the legitimacy of academic attention to the politics of sexual diversity has not kept pace with the readiness of publishers to produce works in the area. To be sure, the surge of work during the 1990s was matched by a growth in academic profile. The American Political Science Association (APSA) recognized a Committee on the Status of Lesbians and Gays in the Profession in the early 1990s, following the earlier formation of an LGBT caucus. This produced more equitable policies, studies of scholarly inclusiveness (by the APSA in 1993–1995), and increased room for specialists in LGBT issues to present their work. The 1990s and 2000s also saw the creation and growth of academic programs and research centers focusing on sexual diversity, the largest and most successful being the Center for Lesbian and Gay Studies (CLAGS) at the City University of New York.

Well into the 2000s, however, sexuality was still viewed as a marginal area, much as gender had been in previous decades. Undergraduate texts in political science in all countries only rarely referred to LGBT issues. Social
Politics, Gender

Science literature on these questions has routinely been pigeonholed with other gay-related material and seldom seen as contributing to more general understanding of public policy, social movements, voting behavior, or legislative politics.

**POLITICS, GENDER**

*Gender politics* is a multifaceted concept in the social sciences. As a term it is used to refer to a wide range of phenomena, stemming from multiple and even competing meanings of *gender* and *politics*. Its definition is further complicated by the emergence of similar and related phrases like *women and politics*, *gender and politics*, and the *politics of gender*. This complexity indicates ongoing conceptual debates within research on gender and politics. At the same time, it reflects theoretical and empirical developments as the study of gender politics has evolved and grown to encompass a broad and heterogeneous set of topics.

**DEFINITIONS**

Several definitions are necessary in order to grasp the scope and content of gender politics as a concept and a field of study. At the most basic level, it is crucial to distinguish between sex, gender, and sexuality. In their most common usages, sex denotes biological differences between men and women as male and female, gender describes the social meanings given to sexual differences through notions of masculine and feminine, and sexuality refers to sexual relations and questions of sexual orientation. However, definitions of all three of these terms, as
well as the connections between them, are subject to a great deal of confusion and debate.

First, there is a tendency to identify all three terms with only one side of the dichotomies they represent: sex is often equated with female, gender with feminine, and sexuality with homosexuality. The result is that sex and gender are often treated as synonymous with women, while sexuality is considered only in relation to gays, lesbians, bisexuals, transsexuals, and transgendered individuals. Second, there are important disagreements on the ways in which sex, gender, and sexuality inform and are linked to one another. Although the binaries of sex and gender assume heterosexuality, for example, other sexual orientations raise questions about the necessary connections between male and masculine and female and feminine. These patterns intersect with debates about the causal relations between these terms: Although some argue that sex produces gender which leads to sexuality, others suggest that gender and compulsory heterosexuality give rise to distinctions on the basis of sex.

Parallel to these discussions, feminists and others have pioneered new uses for the term politics. Although many people employ this word to refer to formal political processes, like government and elections, politics has assumed at least two additional meanings in the last several decades. On the one hand, women’s movement activists have expanded its range to encompass informal politics and the dynamics of everyday life. They insist that social movements are a form of political participation on a par with engagement inside the state. At the same time, they draw attention to the power relations that permeate all levels of social life, including relations within the private sphere of home and family. For them, “the personal is political.” On the other hand, feminist and postmodern theorists have adopted a broader notion of politics as any instance or manifestation of power relations. They are thus interested not only in the politics of the state and the politics of social movements, but also in the politics of language, the politics of exchange, and the politics of representation, to give but a few examples.

These debates, in turn, lead to a range of different understandings of the term gender politics and cause it to be confused with related terms like women and politics, gender and politics, and the politics of gender. Although many people use these phrases interchangeably, it is possible—on the basis of the theoretical distinctions outlined above—to carve out some general differences between them. Women and politics involves the study of various aspects of women’s political activity, whether this entails engagement in social movements, political parties, elected assemblies, or the state. Gender and politics covers many of these same topics, but in addition, implies attention to masculinities and femininities, as well as relations between men and women, as they operate in various political arenas. The politics of gender, finally, comprises a closer look at the power relations behind definitions of—and presumed causal relations between—sex, gender, and sexuality. In comparison, gender politics may refer to any and all of these distinct foci of investigation.

Individual disciplines take up the study of gender politics in various ways, depending on their core research interests and theoretical frameworks. Because various currents in sociology, anthropology, and philosophy embrace broad definitions of politics, scholars in these fields use the term gender politics in many different ways to refer to the study of women and politics, gender and politics, and the politics of gender. Ironically, political scientists tend to adopt a much narrower definition of gender politics to refer only to the study of women and politics and gender and politics, where the term politics encompasses only formal and informal political processes, to the exclusion of questions about broader power relations. Even this more restricted focus, however, has produced a wide range of literature that over time has expanded and evolved in terms of theoretical approaches and fields of empirical research.

APPROACHES

As feminist theorists have developed sex and gender as analytical categories, scholars in political science have elaborated a series of approaches for analyzing the sexed and gendered nature of political life. The first phase of research on gender politics involved highlighting women’s exclusion from formal politics and then incorporating women into existing political frameworks. It was thus guided by an “add women and stir” approach: Using sex and gender as synonyms for women, it sought to include women but did not question the male norm implicit in reigning understandings of political processes.

Recognizing the limits of this approach, the second phase shifted its attention to the activities of women as women and analyzed their participation in formal and informal politics. Although many scholars continued to employ the term gender when they discussed only women, a growing number also began to use it to refer to relations between men and women in order to study how the form and content of politics reflect and shape inequalities. The third and current phase extends these insights to explore how ideas about sex and gender permeate all aspects of political life, sometimes—but not always—with the intent to break down these dichotomies. This work introduces, for the first time, the importance of studying masculinities as well as femininities in politics. It also investigates how political science itself may be gendered in terms of its concepts, definitions, theories, and methods.

The main theoretical innovation that emerges over the course of these stages is a multifaceted shift in focus
from sex to gender. In light of the different definitions attributed to these terms, analysts ascribe at least three distinct meanings to this shift. The first is a move away from biological sex, or the notion that men and women are binary opposites, toward socially constructed gender identities, or the idea that masculinity and femininity constitute features that exist along a continuum. The second is a move away from exclusive concern with women in politics and public policy toward greater attention to the impact of masculinities and femininities, as well as relations between men and women, on political inputs and outcomes. The third is a move away from sex as one of many possible variables in political science toward gender as a concept that forces a fundamental reexamination of core features of political life.

All three aspects of the shift from sex to gender, nonetheless, are in some sense incomplete. For one, mainstream and feminist researchers find that while indicators for sex are relatively straightforward to incorporate into political analysis, those for gender are much more complicated. This is partly because sex refers to biological markers that are relatively unambiguous, while gender denotes social meanings that may vary a great deal within and across particular contexts. However, this is also due to difficulties that many people experience in grasping that the relationship between sex and gender is not a perfect one. Secondly, many feminists are hesitant to abandon sex in favor of gender. As the two concepts are not equivalent, these scholars argue that both are crucial to good research design, whether the purpose is to analyze men and women or masculinities and femininities as these play out in various kinds of political arenas.

**FIELDS OF RESEARCH**

Attempts to expand the scope of politics to include formal and informal political processes are reflected in the areas of empirical research on gender politics in political science. Seeking to break down dichotomies of public versus private spheres and formal versus informal politics, these scholars have explored the effects of sex and gender on a broad range of political activities. Focused on women specifically, they have examined women and voting, in terms of the right to vote, the implications of delayed suffrage, and gender gaps in voting support; women and social movements, in terms of participation in social movements, women’s movements, and feminist movements; women and political parties, in terms of candidate selection and other aspects of party politics; and women and parliaments, in terms of access to political office, behavior in political office, and impact on public policy.

Turning to the products of political processes, gender politics researchers have theorized the role of the state in reflecting and shaping gender relations. They analyze how states contribute to the reproduction of gender hierarchies, or alternatively, lead to changes in patterns of inequality through different kinds of public policies. Attentive to variations across countries, they note the ways in which such policies make implicit or explicit assumptions about men and women and identity—or ignore—certain questions as women’s issues. The possibilities of exploring other definitions of politics and incorporating interactions with other identities, combined with the already multifaceted nature of sex and gender, ensure that all six of these areas will remain vibrant areas for future research.

**POLITICS, IDENTITY**

Identity politics is a term that first came into usage in the 1970s to refer to the view that social identities, such as race, ethnicity, sexuality, and gender, have an important influence on an individual’s political motivations, affiliations, and political commitments. The term quickly moved from a neutral description to primarily a pejorative and began to refer to the practices of narrow interest-group politics, separatism, and the practice of assessing a person’s politics on the basis of his or her identity alone.
In the 1990s both the concept and the practice of identity politics began to be vigorously defended primarily by theorists working on identity-based political movements or movements against identity-based forms of oppression.

Most consider the locus classicus of the concept of identity politics to be the Combahee River Collective Statement written in 1978. The term had been used in public discourse in the Left before this time, but this was the first place that it received an explicit formulation. In this statement, identity politics refers to the idea that the identity of political agents and theorists will have an impact on both the political work they choose to pursue and also on its effectiveness.

The Combahee River Collective was composed of African American women who believed that there did not yet exist a social theory or political movement that fully and accurately reflected the conditions of African American women's lives. They argued that African American women needed to develop such a theory and movement themselves, that they would be the group most motivated to do so, and that they would be the group with the knowledge base from which to develop the specific social analyses applicable to their form of intersectional oppression. They made a specific point of stating that they were not separatists and in fact supported coalition work, particularly with those in the feminist and antiracist movements. They also stated that they did not reject the utility of more general social theories of oppression, such as Marxism. Yet they held that a special focus on black women's lives by black women themselves was necessary to yield new insights and practices. Their defense of this latter claim was based on the state of the social movements of that time, in which the specific oppression of African American women was not pursued by either feminism in general or by the antiracist movements.

The concept of identity assumed by the Combahee River Collective was an intersectional and complex one. They did not assume that all women or all African Americans have the same political motivations or goals, hence their formation of this separate group. Many members also were lesbians and experienced marginalization as well as homophobia in other groups. Despite their experience with the complexities of group identity, they nonetheless asserted that “we believe that the most profound and potentially the most radical politics come directly out of our own identity, as opposed to working to end someone else’s oppression” (Combahee River Collective 1978, p. 365).

From this rather careful and cautious explanation of the relationship between identity and politics—a relationship conceived of as philosophical as well as political—the term identity politics began to be associated with the identity-based splits and sectarianism that rippled throughout the civil rights, gay and lesbian, women’s, and student movements of the 1960s and 1970s. Most notably this included the removal of whites from the Student Nonviolent Coordinating Committee that occurred in the mid-1960s and the gay-straight split that occurred in the women’s movement in the early 1970s. Splitting organizations along identity lines was attributed to identity politics. This connotation of the term may already have been in circulation when the Combahee River Collective first formed, motivating them to give an explanation and defense of the identity-based form their collective took.

CRITICS OF IDENTITY POLITICS

From the 1980s on both liberal and left political theorists began to critique the concept as based on simplistic notions of identity and narrow conceptions of solidarity and as maintaining a focus on victimization rather than on effective solutions. These theorists argued that identity politics was an obstacle to the work of creating trust across differences of identity, which is necessary for coalitions and class-based movements. They argued further that it had detrimental effects within identity defined groups themselves, such as enforced conformism within the group, a policing of the group’s boundaries, and a hampering of the expression of and debate over internal political differences within groups.

Leading liberals such as Arthur Schlesinger Jr. criticized identity politics for making a cult of identity that derailed the trend that had been growing up until the 1960s toward a melting-pot society. Other liberals also worried that identity politics in a multiethnic society would disable democracy by transforming the arena of public political discourse from a shared concern over the common good to a negotiation between interest groups locked in battle. Liberals also predicted that identity politics would lead to a Balkanization of the political landscape and an increase in civil strife, possibly including the kind of violence that occurred in the former Yugoslavia in the 1990s.

Leftists expressed the concern that identity politics had derailed the possibility of forming a class-based progressive movement that could unite around critical issues of economic injustice. Race- and gender-based movements are multi-class, they argued, and so cannot take up a working-class agenda. Many philosophers also entered the debate, especially those influenced by French post-structuralism, to argue that the concept of identity being assumed by proponents of identity politics is an illusion of coherence and unity based perhaps on a form of psychological pathology. Identity concepts assume a homogeneity of experience and political interests where none exists, and this is why identity-based movements must enforce homogeneity and police the borders around identities to keep out those with intersectional identities who might
have a different set of political priorities. Some ethnic theorists, such as Paul Gilroy, united with this critique, arguing that identity politics is an understandable but pointless reaction to modernist pressures that transform identities and diminish their significance.

IDENTITY-BASED AND PROGRESSIVE

In response to these concerns a number of theorists, especially in ethnic studies, argue that identity-based political movements—such as the abolitionist movement and civil rights movement—have been among the main forces expanding democratization and developing progressive politics. Identity-based movements have improved the inclusiveness of class-based movements so that the interests of nonwhite and women workers are also represented. The white male union leaders would not have come to these more inclusive agendas on their own without being pushed by the various caucus groups within the labor movement that were organized around identity. Identity politics was a necessary part of the strategy to overcome identity-based forms of oppression, to ensure an inclusive political agenda, to develop a more thorough analysis of social oppression, and to show the equality of all people as leaders and intellectuals.

A number of ethnographic studies reveal that identity politics do not always lead to separatism or enforced conformity and that we need to develop a typology of identity-based movements in order to distinguish between different forms with different effects. Mobilizing on the basis of identity can bring new actors to political participation and thus work against the passivity of victimized notions of identity. Under extreme repression, identity groups may curtail the expression of internal differences, but this is not inherent to identity-based movements.

The concepts of identity assumed by the parties to this debate vary widely. Some theorists on both sides of the debate assume that identities are like interest groups with uniform political interests or that members of identity groups are identifiable by their shared practices, preferences, and beliefs. Other theorists, such as Satya P. Mohanty, Paula M. L. Moya, and Linda Martín Alcoff, argue that identities are historically fluid, intersectional, and heterogeneous and thus a starting place rather than the endpoint of politics. Nonetheless, identities are important indices of experience and provide epistemic resources for social analysis.

POLITICS, LATINO

The terms Latino and Hispanic are the most accepted words for a diverse population of people with linguistic, geographic, and historical similarities, but the terms are wrought more for practical convenience than descriptive clarity. The literature on Latino politics has stressed the differences between the various Latino groups since the Latino National Political Survey in 1989, the first major national survey specifically targeting Latinos. National debates over immigration policy in 1994 and 2006, however, demonstrate that despite their diversity, Latinos are a group of people distinguishable, for better or worse, by both Latinos and the electorate at-large.

LATINO ELECTORAL PARTICIPATION

The litmus test of civic participation for any group is their level of electoral turnout. David Leal, Matt A. Barreto, Jongho Lee, and Rodolfo O. de la Garza noted in “The Latino Vote in the 2004 Election” that Latino voter turnout “surged from 5.9 million in 2000 to at least 7 million in 2004” (2005, p. 41). Increasing levels of electoral participation may suggest a comparative increase in socioeconomic status, higher levels of personal interest, greater levels of civic engagement, or a greater effort on the part of the establishment to recruit Latinos. The greatest impact Latinos have had on American politics comes from speculation regarding the Latino vote, but the numbers paint a considerably different picture. Table 1 illustrates U.S. Census Bureau reports showing that registration and participation rates among Latino citizens and non-citizens have hardly changed since 1980. The increase in the raw numbers of Hispanics voting from 1980 to 2004 is attributable almost entirely to population growth, considered to be the driving force of Latino politics.

LATINOS’ RELATIONSHIP WITH THE AMERICAN POLITICAL SYSTEM

In their work The Chicano Political Experience F. Chris Garcia and Rodolfo de la Garza illustrated four models to explain the relationship between Latinos and American society in 1977: pluralism, internal colonialism, and elitism. Rodney Hero later contributed his influential description of a two-tiered pluralistic society in 1992 with Latinos and the U.S. Political System.

Under the pluralist framework, groups vie with one another on a competitive field, each with their own advantages, resources, and centers of power where there are multiple access points to influence the political system. The most compelling argument for a pluralistic model is Lawrence H. Fuch's The American Kaleidoscope (1990), in which he parallels the Latino immigrant experience and past immigrants who are now largely integrated into the political power structure.

By contrast, internal colonialism claims a sociopolitical system in which Latinos are dominated and exploited by other groups, even though they may have the same formal legal status of the dominant group. It emphasizes the integration of historically racist relationships between the dominant non-Latino majority and Latinos into the fabric of the political system. Distinctions from the dominant group are seen to have negative or inferior qualities, and the stereotypes of Latinos are embedded into the institutions of the social and political systems, from the electoral system to the financial and educational infrastructure.

The elitism perspective asserts that there is a privileged class of people who enjoy superior resources with racially generated attachments that serve to further appropriate the privileged class to their position at the top. The elitism model depends less on racial distinctions and more on class differences to explain the unequal distribution of power and resources that characterizes the Latino masses. Elitism is also different in that it does account for some growth in Latino influence, but Latino elites are not likely to resemble the Latino masses and are more likely to resemble their non-Latino elite cohort.

Hero argues that there is a large segment of Latinos who are structurally cut off from the opportunities that are available to the mainstream, despite the success stories. He describes a compelling perspective on Latinos’ relationship with the American system, a two-tiered pluralistic society in which there is a conventional population that operates in the traditional patterns that most immigrant groups do, and a second tier that consists of a political and social subclass whose position is supported by historical and cultural inequalities that have become embedded into the fabric of the structural system. Two-tiered pluralism is a complex framework that consists of a political system that is formally unrestricting but exists within a social system that is informally constrained by negative historical relationships.

The 1994 Proposition 187 debate in California illustrates Hero’s model, as Latinos were politically fully engaged, but largely helpless in their efforts to prevent Proposition 187 from passing decisively. Although Proposition 187 was deemed unconstitutional, the anti-immigration movement throughout the United States remains robust into the mid-2000s and illustrates the relationship Hero draws between Latinos and the American political and social systems. Latinos may have a legal status equal to the majority, but the continued poverty and social status of Latinos is a function of continually having
to defend themselves against the mainstream, preventing them from tapping into valuable social resources.

ASSESSING LATINOS’ RELATIONSHIP WITH THE AMERICAN SYSTEM

As noted above, the rate of Latino electoral participation has not changed significantly since 1980, just three years after Garcia and de la Garza outlined their models on the relationship between Latinos and the American system. After reflecting on nearly three decades of literature on Latino politics, however, de la Garza believes Latinos do indeed fit into the pluralistic model. He points out that this was not always the case and if he were to make the same assessment back in 1977, pluralism would not have been his first choice.

The empirical evidence since 1977 has swayed his opinion, suggesting that the distasteful realities of the Latino experience have indeed improved. One reason for de la Garza’s initial judgment in 1977 might have been the available models at the time, which were used to explain the how, why, and whom of Latino politics. Up until 1977, the field of political behavior had largely settled into two general camps, rational actor theory and socioeconomic status theory. These theories are not exclusive, but in their stages of development before 1977, neither could sufficiently explain the position of Latinos in the American system.

The literature on Latino politics up to that point had been guided by the scholarship on African American politics and focused on grassroots movements that tended to skew the perspective toward the inequalities born out of the social and political climate of the time. These perspectives focused on the effects of socioeconomic status (SES), social capital, institutional trust, group identity, and group relations. The development of these models provides researchers with the tools to better understand the forces behind Latino politics.

Up until 1977, the strong impact that SES had on political participation was a truism in the field. The rational actor model assigned higher stakes to the socially privileged because they had a greater incentive to take an active role in a system from which they benefited. The socioeconomic status model had established the connection between participation and higher levels of SES in a variety of national and international surveys at the time. Whether it was out of civic-minded duty or rational self-interest, Latinos could hardly be seen to have had much of an incentive to participate.

Given the low SES of Latinos it was not difficult to speculate why Latinos did not participate, but the empirical models had yet to capture the depth of this dimension in Latino politics. While Latinos simply did not have the resources to effectively participate, from a theoretical perspective one could only speculate as to how Latinos would be able to exact change on the political system.

This hole in the literature left a heavy burden on pluralism to explain the unequal distribution of resources, and the literature had hardly given much promise in Latinos’ ability to traverse the social barriers that were clearly evident at the time. Elitism and internal colonialism offered the best explanation for the position of Latinos in the American system almost by default. But if the relative participation rates have not changed much since 1977, what evidence have the empirical models provided that might convince de la Garza that Latinos live in a pluralistic society?

One potential answer is that the field of Latino politics has learned that Latinos behave no differently than do non-Latinos and that ethnicity in and of itself has little direct effect on the participation rates of Latinos. Carole J. Uhlaner, Bruce E. Cain, and D. Roderick Kiewiet concluded in their 1989 article “Political Participation of Ethnic Minorities in the 1980s” that “Latino activity rates appear no lower than those of non-Hispanic whites once demographic factors and related determinants of participation are controlled” (p. 217). The behavioral models have taken a greater account of the experiences and obstacles that faced Latinos and are able to control for many of the speculative factors that had not been empirically established, such as different patterns of civic voluntarism and an underdeveloped elite-driven organizational structure necessary for effective mobilization.

More important, events since 1977 have provided many examples of Latino political success and the large Latino population has made it easier to witness a growing Latino middle class. Because of this, it is difficult to jus-
tify the internal colonialism model, and Hero’s two-tiered pluralism was an attempt to rectify the internal colonialism model with the facts on the ground. Two-tiered pluralism concedes what at that point could not be argued anymore, that Latinos had indeed reached legal parity with the majority, while still relying on historical racism to explain the differences in socioeconomic status. The future may prove two-tiered pluralism to be wrong, but until then, it is still the best framework available to explain why Latinos behave the same as non-Latinos given the same characteristics, and why they do not reap identical benefits as Anglos do from the same political actions.

POLITICS, SOUTHERN

In politics, religion, and culture, the South is arguably the United States’ most unique region. Southerners, particularly native-born white southerners, have a collective consciousness and attachment to history that exceeds that found in other regions, such as the upper Midwest, New England, and the West. A native-born Connecticut or Massachusetts resident is far less likely to identify as a “New Engander” than a native-born South Carolinian or Mississippian is to identify as a southerner. Historian David Goldfield refers to the drive among some white southerners to preserve some elements of the past as “still fighting the Civil War” in his 2002 book of the same title. While not unique to the region, several elements, including military traditions, a “culture of honor,” attachment to traditional gender roles, and fundamentalist Christianity, have striking support in much of the South compared to the rest of the nation. These elements materially influence politics, and southern politics, always distinctive in the past, remains distinctive in the twenty-first century.

Which states make up the South? This question has no single agreed-upon answer, and opinions vary. Many political-science datasets include data from only the eleven former Confederate states. For the purposes of this entry, the South includes thirteen states: Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, Tennessee, Oklahoma, and Kentucky. The first eleven of these states were the former Confederate states—those that seceded from the Union during the Civil War. Oklahoma and Kentucky, though not former Confederate states, have cultural and political features—for example, large Southern Baptist populations—that arguably warrant their consideration as southern states as well.

CLASSIC AND CONTEMPORARY STUDIES OF SOUTHERN POLITICS

The distinctive nature of southern politics is implicitly acknowledged in the two most widely cited scholarly studies on the topic: V. O. Key’s Southern Politics in State and Nation (1949), and Merle Black and Earl Black’s Politics and Society in the South (1987). Key wrote when southern whites remained economically, socially, and politically dominant over blacks—as they had been since the end of slavery in 1865. Southern whites used their control over government to ensure and perpetuate racial segregation and impose rampant, official racial discrimination on wide swaths of social institutions: education, housing, employment, voting, and criminal justice, to name a few. While racial discrimination also existed in much of the North, it was more pervasive and severe, and more a product of government actions, in the South. As Key notes, most of the South was under one-party Democratic control, and most political conflict in southern states centered on factions within the Democratic Party. Factions sometimes centered on regions within states (with conflict between Delta and “hills” factions in Mississippi). In other cases, factions centered on personalities (such as the flamboyantly racist “Pitchfork Ben” Tillman of South
Carolina and Theodore Bilbo of Mississippi) or other interests, such as textile mill owners in North and South Carolina and the “big mules” of timber, iron and steel, coal, insurance, and utilities in Alabama.

Although factions sometimes splintered the Democratic Party, on racial issues there was little disagreement among southern whites at midcentury. Racial discrimination and segregation were entrenched; any (white) elected official who dared to challenge either faced severe social ostracism, economic reprisals, and certain defeat in the next election. Southern blacks had virtually no political power, and voting discrimination along with threatened and actual violence effectively deprived them of voting rights—especially in the Deep South states of Louisiana, Mississippi, Alabama, Georgia, and South Carolina. With elected officials virtually all white Democrats and with Republicans reviled by whites as the party of Lincoln, the Union, and racial equality, there was little impetus for racial change. Thus, Key concluded, “The race issue broadly defined must be considered as the number one problem on the southern agenda. Lacking a solution for it, all else fails” (1949, p. 675).

In 1987, political scientists (and twin brothers) Merle Black and Earl Black published Politics and Society in the South. By then, much had changed in southern politics. Federal court decisions and laws effectively guaranteed civil rights in housing, education, and employment, and the 1965 Voting Rights Act had ended various egregious practices that promoted voting discrimination and the dilution of black political power. By 1987, they wrote, the Democratic Party’s monopoly in southern politics had ended, replaced by a competitive two-party system, with Republicans becoming dominant in presidential electoral votes as early as 1984, when Ronald Reagan swept every southern state. The authors also noted a decided “conservative advantage” in white public opinion: White southerners identifying as conservatives outnumbered those identifying as liberals by nearly a three-to-one margin (Black and Black 1987, p. 218, Table 10.1). This and similar findings, they argued, meant likely continued Republican gains in southern governorships, state legislatures, and delegations in the U.S. House and Senate. Black and Black’s later (2002) study confirmed their suspicions, documenting strong Republican growth in the region.

The studies by Key and Black and Black are widely considered the most systematic investigations of southern politics. However, other studies also deserve note. Numan Bartley and Hugh Graham’s Southern Politics and the Second Reconstruction (1975) was written less than ten years after the civil rights movement fundamentally reorganized race relations, and at a time when Republicans were beginning to erode the Democratic one-party monopoly that had been entrenched from 1890 to 1950. A more recent study is journalist Peter Applebome’s Dixie Rising: How the South Is Shaping American Values, Politics and Culture (1997). Applebome’s account is rich with historical observations, economic and social data, and anecdotal evidence derived from personal observation and travels in locales such as Cobb County, Georgia; Charlotte, North Carolina; Columbia, South Carolina; and Nashville, Tennessee. Finally, some political scientists have published more focused studies of southern politics. Book-length studies in this tradition include Oran Smith’s The Rise of Baptist Republicanism (1997), James Glaser’s Race, Campaign Politics, and the Realignment in the South (1996), Merle Black and Earl Black’s The Rise of Southern Republicans (2002), and Glaser’s The Hand of the Past in Contemporary Southern Politics (2005). Clearly, the study of southern politics has matured into a well-defined subfield in political science, as much as southern history is a well-known specialty among historians.

THE CIVIL WAR, RECONSTRUCTION, DISENFRANCHISEMENT, AND JIM CROW
The Civil War (1861–1865) was a searing experience nationwide, but its physical devastation and psychological scars fell especially hard on the South. As the losing side, southerners saw their region ravaged by the Union army, with widespread destruction of and damage to homes, crops, and livelihoods. In the war’s aftermath, federal troops occupied southern state capitals for over a decade—a profoundly humiliating experience for a region that already had lost a war and seen federal officials force an end to slavery, the dominant economic system of much of the region. Congress passed the Thirteenth Amendment, outlawing slavery; the Fourteenth Amendment, guaranteeing equal protection under the law, among other things; and the Fifteenth Amendment, aimed at preventing voting discrimination against blacks and freed slaves. During the Reconstruction era (1865–1877), Republicans dominated national politics and forced white southerners to accept the end of slavery, occupation by perceived federal invaders, and, sometimes, southern black elected officials. In Mississippi, Hiram Revels became the first African American to serve in the U.S. Senate (1870–1871). As Black and Black note:

[The Democratic Party] gave southern whites something to love, honor and glorify; Republicanism gave them something to hate, despise and excoriate. Republicans were irredeemably identified with a long series of outrages against the white South—the Civil War, abolition of slavery, Reconstruction, threats of renewed fed-
eral intervention, and the exploitation of the South's vulnerable economic condition. Except in a few (mainly mountainous) areas where grassroots Republicanism persisted, public support for the party of Lincoln entailed the stigma of providing aid and comfort to the region's historical enemy. (1987, pp. 233–234)

For black southerners, Reconstruction was a brief era of relatively improved conditions. Blacks' living conditions remained difficult, but under federal control of the South, they had more freedom to pursue their destinies and faced less severe discrimination in doing so. For white southerners, Reconstruction was an uninterrupted regional nightmare. Whites' obsession was to expel the federal "invaders," end their "radical" control, and reestablish "home rule"—local control over their social, political, and economic affairs. Above all else, southern whites fought to reestablish white domination and the subjugation of southern blacks.

In 1877, the federal army withdrew from southern state capitals, bringing Reconstruction to an end. The era that followed was dubbed "Redemption" by southern whites. But for most southern blacks, "Redemption" meant the return, in different form, of the nightmarish conditions of the slavery era, including white-imposed economic exploitation through the sharecropping system. Whites sought to reestablish white Democratic control and expel the hated Republican Party and anyone friendly to it from the political system. By 1890, using a combination of terror and violence, widespread electoral fraud, racial demagoguery, and pervasive social and economic pressure on any reluctant friends, family, and neighbors, white conservative Democrats succeeded in effectively eliminating Republican competition in southern politics. The resulting virtual one-party Democratic stranglehold in southern politics lasted from 1890 to 1965.

For southern blacks, the consequences were devastating socially, politically, and economically. With a virtually unbreakable lock on political power, white Democrats imposed social, economic, and political discrimination on blacks on a colossal scale. Black southerners were shut out of political power, as whites imposed discriminatory poll taxes, literacy tests, the grandfather clause, and the white primary to perpetuate white domination and crush black opposition. These electoral tests and devices frequently were applied arbitrarily by hostile white registrars to ensure that few if any blacks could register to vote. For blacks, the result was massive disenfranchisement: the often-successful panoply of white efforts to deny voting rights to blacks. Blacks who managed to evade official voting discrimination and actually register to vote faced harassment, threats, violence, and economic retaliation. Arbitrary evictions, job terminations, and blacklisting, ensuring that no other local employers would ever hire the person, often effectively "persuaded" blacks to avoid challenging white domination and meekly accept their lot. The costs of being an "uppity Negro" in the South—one audacious enough to challenge the racial status quo—were manifold: social ostracism, harassment and persecution by law enforcement, threats, actual violence, and possibly death by lynching. In much of the South, the only real qualification for voting was being white, though the poll tax did disenfranchise many poor whites also.

With blacks shut out of the ranks of elected officials and largely shut out of voting, the establishment of conservative white Democratic "home rule" was complete by 1890. Local and state governments passed Jim Crow laws imposing legal segregation in public schools and places, including restaurants, drinking fountains, theaters, pool halls, parks, train and bus stations, neighborhoods, and more. Blacks also faced economic discrimination; other laws prohibited blacks from holding many types of jobs, typically higher-paying, higher-status jobs. Informal customs and practices strongly reinforced these patterns. White business owners and managers commonly refused to hire blacks at all, or at best hired them only for the most menial and low-paying jobs. Southern textile mills were particularly ruthless in enforcing the color bar in employment, with black mill workers virtually nonexistent. In housing, governments forced blacks to live in segregated, usually deeply impoverished, neighborhoods, and white homeowners would, by custom, refuse to rent or sell to blacks anyway. Restaurants, theaters, libraries, and other establishments commonly refused to serve blacks altogether; colleges and universities refused to enroll them, resulting in the establishment of historically black colleges and universities, some of which still exist. Few whites dared openly sympathize with blacks or support efforts to combat segregation and discrimination. A white seen as pro-black could expect to be branded a "nigger lover" and faced the same threats, economic reprisals, and violence that "uppity Negroes" did. As Black and Black point out, even well into the twentieth century, southern whites were obsessed with maintaining "home rule"—local control over race relations:

Early in [the twentieth] century, most white southerners looked upon the rest of the nation—generally lumped together as Yankees—with abiding hostility and suspicion. Unable to forget or forgive the nightmare of war, defeat, and occupation, most whites shared the conviction that nonsoutherners must never again be allowed to interfere with southern racial practices. Acting almost as if it were an independent nation, the South pursued deterrence of outside intervention in race relations as the paramount objective of its "foreign" policy. (1987, p. 233)
THE CIVIL RIGHTS MOVEMENT 
AND ITS POLITICAL 
CONSEQUENCES

In the early twentieth century, the U.S. Supreme Court overturned some racially discriminatory voting practices. In 1915, the Court overturned the grandfather clause, and in 1944, it struck down the white primary. However, other forms of voting discrimination persisted, and until 1965, federal law did little to prevent it.

The first major federal civil rights action of the twentieth century was the Supreme Court’s Brown v. Board of Education ruling in 1954. Overturning an 1896 legal doctrine allowing “separate but equal” public facilities, the Court ruled that racial segregation in public schools was inherently unequal. The ruling and its 1955 companion ruling (Brown II, ordering officials to desegregate public schools “with all deliberate speed”) exploded like bombshells in the southern political landscape. Southern officials responded with outrage and unvarnished defiance. The “Massive Resistance” campaign mounted by southern officials to oppose school desegregation was intense and unrelenting. From 1959 to 1964, Prince Edward County, Virginia, closed its public schools altogether to avoid desegregation and provided money to white parents to send their children to private, whites-only schools. Meanwhile, most black children were locked out of an education for five years. In 1964, nearly 98 percent of southern black children still attended segregated schools. Only after more court orders did some districts comply with the Brown rulings.

During the early 1960s, efforts to integrate southern schools and universities and register blacks to vote provoked waves of violence. In 1960, sit-in demonstrators seeking integrated lunch counters faced attacks and violence. In 1961, freedom riders seeking to integrate public transportation faced more violence and beatings. In 1962, when James Meredith integrated the University of Mississippi, thousands of segregationists rioted, resulting in two deaths and mobilization of thousands of National Guard troops to restore order. In 1963, white supremacists bombed a black church in Birmingham, Alabama, killing four little girls, and NAACP leader Medgar Evers was murdered in his driveway in Jackson, Mississippi. In 1964, three civil rights workers were murdered near Philadelphia, Mississippi. In 1965, Alabama state troopers attacked unarmed voting-rights marchers with clubs, police dogs, and electric cattle prods. Searing images of these events were broadcast on national television at a time when (by 1964) 97 percent of American households had television sets. The repeated incidents of civil-rights-related violence spurred calls for concerted federal action on civil rights from the public and in Congress.

In 1964, southern members of Congress mounted ferocious opposition, including a Senate filibuster, to the 1964 Civil Rights Act. But northern Republicans and Democrats overcame the filibuster, and President Lyndon B. Johnson signed the Civil Rights Act into law in July 1964. The Civil Rights Act banned employment discrimination for most employers, and banned racial segregation in public facilities, including private businesses that serve the public such as restaurants, theaters, pool halls, hotels, and motels. In 1965, Congress passed the Voting Rights Act, which placed most of the South under federal supervision of its voting and elections laws. The Voting Rights Act banned tests or devices such as “literacy tests, educational requirements [or] good character tests” and other arbitrary actions by local registrars that promoted racial discrimination in voting. The act required covered states and districts to gain prior federal approval before implementing any changes in election laws or voting requirements. The act also banned racially discriminatory efforts to dilute black voting or political power, such as some “at large” schemes for drawing electoral districts to prevent black candidates from being elected. Finally, the Voting Rights Act allowed federal registrars to replace local registrars that continued discriminatory voting practices. The passage of the Twenty-fourth Amendment (1964) banning poll taxes lent further impetus to the drive to guarantee equal voting rights for blacks.

Overall, the Voting Rights Act was tremendously effective. In 1960, 61 percent of southern whites but only 29 percent of southern blacks were registered to vote. Racial discrimination in voting was much less rampant in Rim South states such as Tennessee and Kentucky than in the Deep South, especially Mississippi and Alabama. Although small racial disparities in voter registration and turnout remain as of 2007, differences in income and education account for most such disparities.

Politically, the civil rights movement generated shock waves that permeated southern and national politics. As political scientists Edward Carmines and James Stimson (1989) demonstrate, the civil rights movement triggered a polarization of the Democratic and Republican parties on racial issues, with Democrats moving leftward to embrace racially egalitarian policies and Republicans moving sharply rightward to oppose them. This process was already well under way during the 1964 presidential campaign. Abandoning the Republicans’ historical moderation on racial issues, the 1964 Republican nominee, Senator Barry Goldwater of Arizona, openly opposed federal civil rights laws. Goldwater’s position was not racist; he neither openly vilified blacks nor expressed support for negative racial stereotypes as southern segregationists had done for decades. Instead, Goldwater couched his concern in “states’ rights” terms: In his view, civil rights policy was best decided by local and state governments, not the fed-
eral government. This was an enormously appealing position for white southerners, and Goldwater cracked the Democrats’ monopoly on the South by winning five southern states. Goldwater’s position was politically disastrous in the rest of the country, however, and President Lyndon Johnson won reelection by a landslide. After 1964, Republicans began openly pursuing a “southern strategy” of appealing to white southerners by opposing vigorous implementation of civil rights laws, embracing “law and order” campaign themes in the 1968 election, tying Democrats to unpopular groups such as Vietnam War protesters, hippies, black militants, and radical feminists, and using racially charged appeals on such issues as welfare, crime, and affirmative action to loosen white southerners’ historical attachment to the Democratic Party. In 1968, Alabama governor George Wallace also ran for the presidency and won several southern states, embracing similar “law and order” and culturally conservative themes. Although he was a Democrat, Wallace’s themes are often echoed in southern politics—but much more often by southern Republicans than southern Democrats.

“STATES’ RIGHTS” APPEALS: ENDURING AND SELECTIVE
The states’ rights appeal first introduced by Goldwater in national campaigns was nothing new in southern politics. Before 1964, southern Democrats had long declared allegiance to states’ rights as a socially acceptable code for minimal federal intervention in race relations in the South—and therefore code for white supremacy. Most white southerners readily got the message. White southerners’ disdain for the federal government was part and parcel of an ideology of selective minimalist government that extends to policy areas well outside race relations.

One such unmistakable impact is the region’s tendency to favor a “low-tax, low-service” ethic: lower taxes, fewer government services, less regulation of business, and less government support for the disadvantaged. For example, according to the U.S. House of Representatives (2004), average 2002 monthly TANF (Temporary Assistance to Needy Families) benefits, which are set by state lawmakers, were lowest in the South. The average monthly TANF benefit was $327 nationwide; for the thirteen southern states, the average benefit was $202, and all six states with benefits less than $200 were southern states. The “low-tax, low-service” ethic also means less government regulation of business, for example, in protecting employees from workplace hazards and the environment from pollution. Southern state governors frequently encourage business executives with operations in the North to relocate to the South, touting the region’s “favorable business climate”: lower taxes and minimal regulations on business coupled with right-to-work laws and other policies that discourage workers from joining labor unions.

The tradition of minimalist government in the South prevails on most economic and social welfare issues, but often not on social and moral issues. Southern lawmakers often prefer policies that maximize government activity in promoting “traditional values.” Thus, gay-marriage bans have passed in twenty-seven of the twenty-eight states that have considered them, but in southern states they pass by wider margins, frequently with over 75 percent support—even 86 percent support in Mississippi (2004). Restrictive abortion laws, bans on gay adoption, and efforts to promote prayer in the public schools and Ten Commandments displays in public places are all more common in southern states. Southern elected officials’ proclaimed fealty to “limited government,” then, is selective. Also, conservative southern lawmakers eagerly embrace states’ rights in response to liberal federal policies but not conservative federal policies. Few southern lawmakers objected to then-U.S. Attorney General John Ashcroft’s effort to ensure that federal antidrug laws could overrule state laws allowing medicinal marijuana.

States’ rights is a less potent symbol in southern politics than it was forty or more years ago, when it was widely understood as a desire to preserve white domination over blacks. On issues of federal versus state power, which side embraces states’ rights is often predictable based on whether the federal or state government is advocating the more conservative policy.

RACIAL POLITICS IN THE SOUTH SINCE THE CIVIL RIGHTS ERA
Race remains a notable dividing line in southern politics. This is evident from examining four issues in modern southern politics and campaigns: racial appeals in campaigns (mostly covert racial appeals), Confederate flag controversies, racial redistricting, and the marked racial polarization of southern political parties.

Racial Appeals in Southern Campaigns While not limited to the South, racial appeals in southern campaigns appear with surprising regularity. Sometimes, racial appeals are less than subtle. North Carolina’s Republican senator Jesse Helms was particularly famous for issuing racial appeals. In 1972, Helms, running for the U.S. Senate against a Greek American opponent, produced bumper stickers that read, “Jesse. He’s one of us.” In the 1984 Senate race against then-governor Jim Hunt, Helms complained about “the bloc vote,” referring to North Carolina blacks, who almost universally viewed Helms as hostile to racial equality. Helms scarcely tried to burnish his image among blacks; he launched a long, eventually
unsuccessful crusade against declaring a national holiday for Martin Luther King Jr. In 1990, Helms made his most famous racial appeal against Democrat and former Charlotte mayor Harvey Gantt, an African American. Late in the campaign, Gantt led Helms and appeared poised to win. The Helms campaign produced a commercial attacking Gantt on affirmative action, in which white hands were shown crumpling a job rejection letter as an announcer intoned, “You wanted that job, and you were the best qualified. But they had to give it to a minority because of a racial quota. Is that really fair?” The late Helms ad was widely credited with producing a pro-Helms surge, and Helms won reelection.

Racial appeals in southern campaigns are usually more subtle, and implicit racial issues (especially welfare) have figured prominently. In the 1991 Louisiana governor’s race, Republican candidate David Duke, a former Ku Klux Klan leader, made campaign speeches to virtually all-white audiences attacking the “welfare underclass” —racial code for black welfare recipients. The same year, in Mississippi, Republican Kirk Fordice, then a political unknown, won the governor’s race using an array of implicit racial appeals: opposing quotas, saying that welfare recipients should be forced to work, and attacking policies for coddling criminals. In his 2003 campaign for Mississippi’s governorship, Republican Haley Barbour also raised the welfare issue (and wore Confederate-flag lapel pins on the campaign trail). Political scientists James Glaser (1996) and Tali Mendelberg (2001) provide substantial evidence of the use of implicit racial appeals, which seem particularly common in southern campaigns, where Republicans, in particular, are tempted to “play the race card” by making implicit racial appeals to white voters. Welfare, affirmative action, and crime are common issues that structure implicitly racial appeals. But as Glaser (1996) shows, others include attacking a candidate for “cozying up to” civil rights leaders such as Reverend Jesse Jackson or for not enthusiastically supporting the display of the Confederate flag.

In the 2006 U.S. Senate race in Tennessee, the Republican National Committee (RNC) sponsored a late television advertisement on behalf of Republican candidate Bob Corker against his Democratic opponent, Harold Ford Jr., who is black. The ad was widely criticized as a covert racial appeal on the issue of interracial dating and/or sex—which historically white southerners were obsessed with preventing. Between 1880 and 1950, many black men accused of dating or having sexual relations with white women were summarily lynched, in response to white assumptions that any sexual relations between white women and black men were nonconsensual, resulting from rape. The 2006 Republican ad showed a flirtatious white woman with bare shoulders and no visible other clothing, claiming “I met Harold at the Playboy party!” The ad’s conclusion showed her winking and cooing breathily, “Harold—call me!” Commenting on the Republican ad, political scientist John Geer, a leading analyst of attack advertising, said, “I’ve not met any observer who didn’t immediately say, ‘Oh my gosh! It was a race card.’” As documented by Associated Press reporter Beth Rucker (2006), Geer described the ad as “breaking new ground, and frankly, breaking new lows,” and “mak[ing] the [1988] Willie Horton ad look like child’s play. It is racist. That is the bottom line.” Although RNC chairman Ken Mehlman denied the ad carried racial overtones, Geer and other analysts concluded otherwise. As Rucker notes, Hilary Shelton, an NAACP official, added, “In a Southern state like Tennessee, some stereotypes still exist. There’s very clearly some racial subtext in an ad like that.” Corker won the election, but it is unclear whether the RNC ad changed the outcome.

Confederate Flag Controversies Since 2000, three high-profile Confederate flag controversies have arisen, each over whether southern state governments should support displays of the Confederate battle flag (“stars and bars”) or a state flag design containing it. For some southern whites, the Confederate flag is a symbol of heritage; for most blacks, it is a symbol of racial hatred and white domination. In Mississippi, a 2001 public referendum was held on whether to continue flying the 1894 state flag with a Confederate flag design. Voters approved keeping the Confederate flag design by a surprisingly high 65 percent to 35 percent margin. Not surprisingly, the vote was extremely racially polarized. In two 90 percent white counties, the vote ran 90 percent to 10 percent in favor of keeping the Confederate flag design. In two 80 percent black counties, the vote ran 83 percent to 17 percent in favor of replacing the Confederate design with a new one.

In Georgia in 2002, controversy over Democratic governor Roy Barnes’s handling of the Confederate flag issue contributed to his upset loss to Republican Sonny Perdue in the governor’s race. Confederate veterans’ groups and some Republicans criticized Barnes for pushing changes to the design of Georgia’s state flag to reduce the Confederate emblem’s size. The Sons of Confederate Veterans and other groups argued Barnes should have put the question of redesigning the flag to a public referendum. Perdue’s election put a Republican in the Georgia governor’s office for the first time since Reconstruction.

In South Carolina, too, the flag issue proved electorally damaging to a Democratic governor, Jim Hodges. In 2000, Hodges approved removing the battle flag from atop the state capitol dome and moving it to a less conspicuous location on the capitol grounds. Some analysts viewed Hodges’s action as contributing to his loss in South Carolina’s 2002 governor’s race to Republican Mark
Sanford. The Confederate flag issue, then, appears to offer a case study of the continuing importance of race in southern politics.

**Racial Redistricting** After the 1990 census, civil rights groups expressed concern over the underrepresentation of blacks in Congress and asked state lawmakers to redraw House districts to concentrate black voters in some mostly southern districts. The expectation was to create congressional districts with black majorities to elect more black members of Congress. In the history of congressional elections nationwide, very few majority-white districts have elected minority Congress members. After the 1990 census, some “majority-minority” districts were drawn in various southern states. Majority-minority districts are those in which a minority group (most commonly blacks) makes up a majority of the district’s residents. By 1992, North Carolina, Georgia, and several other states had drawn some majority-minority districts, and these districts did elect black representatives. In 1992 in North Carolina, Melvin Watt and Eva Clayton became the first blacks elected to Congress since Reconstruction, in a state where 22 percent of the population was black. Although most majority-minority districts were intended to elect blacks, some Latino-majority districts were also drawn in Texas and Florida, both states with significant Latino populations.

Some of these racial redistricting efforts were challenged in a series of court cases. In 1996, the Supreme Court ordered the redrawing of North Carolina’s majority-black First and Twelfth Districts, ruling that race was too predominant a factor, and geographical compactness an insufficiently considered factor, in drawing these districts. Melvin Watt’s Twelfth District was redrawn with more compact boundaries, converting it from a majority-black district into a 47 percent black district. Watt retained his congressional seat in the redrawn district. Similarly, in Georgia, the district of Sanford Bishop, an African American, was redrawn to a 39 percent black district after another court challenge.

One impact of these and similar court challenges, then, has been to convert some previously majority-minority districts into “minority-opportunity” districts. In these, the minority group makes up less than a majority of the district’s residents but enough to make it likely that a minority candidate or representative can win elections. As a general rule, in southern districts where blacks make up 45 percent or more of residents, a black candidate has a good chance to win. In districts where less than 30 percent of residents are black, a black candidate is unlikely to win. In southern districts, minority candidates or lawmakers (virtually all Democrats) are likely to win when they can combine (1) a sizable minority presence in the district—40 percent or more is best; (2) high voter turnout from the minority group—best when minority turnout at least equals white turnout; (3) lopsided support from minority-group voters—preferably 85 percent or more; and (4) a significant share of the white vote—preferably 25 percent or more. Most white southerners identify as and vote Republican, and few minority candidates, being overwhelmingly Democrats, can expect to win more than 30 percent of the white vote.

Racial redistricting has had unintended but damaging consequences for southern Democrats. The drawing of districts to concentrate black voters has also pulled blacks out of neighboring districts, giving them larger white majorities. Since most southern whites vote Republican, these neighboring districts have more often elected Republican lawmakers. Racial redistricting, then, has resulted in the election of more Republicans and fewer Democrats to Congress from southern states. Political scientists estimate that racial redistricting has resulted in Democrats losing between seven and eleven U.S. House seats.

The impact on the numbers of southern Democratic lawmakers has not been symmetrical by race. As Earl Black (1998) shows, racial redistricting has resulted in increased representation of black Democrats but also sharply decreased representation of white Democrats holding southern congressional seats. It appears racial redistricting has contributed to sharp increases in the ranks of white Republicans holding southern U.S. House seats. Within and outside the South, the vast majority of blacks identify as Democrats and view Republicans negatively. Some southern Republicans, such as David Duke, Jesse Helms, and Trent Lott, have been openly hostile to black interests. While blacks celebrate the increases in black congressional representation that racial redistricting has produced, most also lament the loss of Democratic strength in southern congressional delegations—to which racial redistricting has also contributed.

**Racial Polarization of Southern Political Parties** In Congress, then, Earl Black (1998) identifies “the newest southern politics”: Black Democrats have become more numerous, white Republicans have become much more numerous, and white Democrats have become much less numerous. Southern congressional delegations are increasingly polarized by race and party combined. Nowhere is this truer than in Texas. After Republicans captured the Texas legislature in the 2002 elections, they forced through a mid-decade redistricting in 2003. In January 2004, before the first election following the redistricting, Texas’s U.S. House delegation consisted of sixteen Democrats and sixteen Republicans. After the 2004 election, the delegation consisted of eleven Democrats (one white, ten black or Latino) and twenty-one Republicans.
(twenty white, one Latino). The plan of maximizing Republican strength in Texas's U.S. House delegation had worked.

In 2006, the U.S. Supreme Court upheld the overall redistricting but overturned the drawing of some district boundaries because the Republican plan diluted Latino voting strength, in violation of the 1965 Voting Rights Act. A panel of judges redrew the boundaries to ensure a larger Latino majority in the district of the only Latino Republican, Henry Bonilla. The new district boundaries were in place for the 2006 elections, in which Bonilla lost his seat to Democrat Ciro Rodriguez, and a white Democrat, Nick Lampson, captured former House Majority Leader Tom DeLay’s former seat near Houston (probably temporarily). As of 2007, racial polarization in Texas's U.S. House delegation remains nearly complete, with two white Democrats, ten black or Latino Democrats, and twenty white Republicans. In the future, both white Democrats face a strong risk of losing their seats, as they represent heavily Republican districts. Texas's U.S. House delegation may soon consist of an all-white Republican majority and an all-nonwhite Democratic minority.

In other southern states, a similar pattern holds. With few exceptions, Republican lawmakers are white (a few from Florida are Cuban American; former representative Bonilla is Mexican American; Oklahoma’s former representative J. C. Watts is black). Democratic lawmakers are more racially diverse, with both white and black lawmakers and a contingent of Latino lawmakers from Texas. In state legislatures, too, Republicans are lopsidedly white while Democrats are more diverse.

In southern electorates, too, racial polarization has been striking. Especially in the Deep South, Republicans have become an overwhelmingly white party. Democrats are more racially diverse, now capturing only a minority of white votes but huge majorities (generally 85% or more) of black votes, and in Texas, sizable majorities of Latino votes. Although the degree of racial polarization of southern parties is striking, the reasons for it are not fully clear. Racial conflicts and attitudes appear to be a contributing factor in pulling southern whites out of the Democratic Party and into the Republican Party—but not the only factor. Other likely contributors include the marked social conservativism, assertive militarism, and preferences for smaller government on economic issues on which southern Republicans virtually unanimously agree. In other words, the Republican Party’s attractiveness to southern whites is partly based on conservative ideology. Among southern Republicans as of 2007, politically moderate views are scarce and liberal views are nonexistent. Conversely, southern Democrats are ideologically more varied. Some (largely majority-minority) districts elect liberal lawmakers, but in more heavily white or conservative districts, Democrats can be moderate or even notably conservative.

As of 2007, race remains a significant factor structuring the southern party system. Political scientists Nicholas Valentino and David Sears (2005) studied the connection between white southerners’ racial attitudes and Republican identification and voting. They found that racial antagonism remains higher among white southerners than white nonsoutherners, and that the association between racial antagonism and Republican voting is stronger among southern whites than nonsouthern whites. Furthermore, that association has grown stronger in recent years among southern whites, but not among nonsouthern whites. These and other findings indicate, then, that racial resentments continue to influence partisanship and voting among southern whites—to the benefit of the Republican Party.

THE CONTOURS OF MODERN SOUTHERN POLITICS

As of 2007, southern politics consists of two-party competition with highly racially polarized parties and a lopsided Republican advantage in federal elections. In state elections, Republicans dominate in some states (especially South Carolina, Georgia, Texas, and Florida), but other states, including Tennessee, Kentucky, Louisiana, and Virginia, show more partisan parity. As of 2007, Democrats have regained ground and even an edge over Republicans in North Carolina and Arkansas. Regionwide, an overwhelmingly white, and sharply and uniformly conservative, Republican Party contests elections against a racially and ideologically more diverse but generally moderate Democratic Party. The Republican Party has dominated the region in presidential elections since 1980 and in congressional elections since 1994. After the 2004 election, Democrats held only four (15%) of the region’s twenty-six U.S. Senate seats and 36 percent of its House seats. The 2006 elections changed matters little; as of 2007, Democrats held 19 percent of the region’s Senate seats and 40 percent of its House seats. In state elections, Democrats have become virtually irrelevant in Florida, Texas, Georgia, and South Carolina. However, Democrats have shown strength in state legislatures in Mississippi, Arkansas, North Carolina, and Alabama and won governor’s races in North Carolina (2004) and Virginia (2005). In 2006, Democrats won a previously Republican-held U.S. Senate seat from Virginia and six previously Republican-held House seats in the region. However, these gains are modest, and some, especially in Texas, are probably temporary. As political scientists Philip Klinkner and Thomas Schaller (2006) demonstrate, Democratic gains in 2006 were concentrated out-
side the South—particularly in the Northeast and Midwest.

The 2006 elections, then, did little to change the major story of southern politics since the civil rights era: the growth of Republican support, virtually entirely among white southerners. Black and Black (1987) identified southern politics as consisting of vigorous two-party competition, with prospects for increasing Republican strength—a prediction that proved correct, as their 2002 follow-up study shows. The Republican trend among southern whites is traceable to several factors, including racial conflicts and resentments, religion and associated social conservatism, urban politics and population changes, “law and order” issues, and southern military traditions.

Racial Conflicts and Resentments As black lawmakers and activists have become more prominent among southern Democrats, it appears a racial backlash has pushed some southern whites out of the Democratic Party because of perceptions that Democrats advocate liberal policies on government social programs and are becoming too pro-black. Whites provide virtually all support for Confederate flag displays, but many southern Democratic officials fear offending blacks by supporting the flag. By emphasizing such issues as welfare and affirmative action, Republicans unmistakably have staked their claim as the home of racial conservatism, which many southern whites find appealing, partly for ideological reasons but, as Valentino and Sears’s (2005) analysis indicates, partly out of continuing racial resentments as well.

Religion and Social Conservatism Like southern politics, southern religion is distinct. By numerous indicators, southerners are more religious than nonsoutherners are. Furthermore, southern religion has two major centers of gravity, according to political scientists John Green, James Guth, Lyman Kellstedt, and Corwin Smidt (2003). Among whites, they refer to the “white Protestant alliance”—especially Southern Baptist and other evangelical Christian traditions, which constitute the center of southern Republican politics. Among African Americans, black churches are an increasingly important source of support for the Democratic Party. The overall impact of these counteracting centers of political gravity is a decided conservative tilt. Southern Baptists are the largest Protestant denomination in the country, at 16.5 million members. Since 1979, the theologically fundamentalist, politically conservative faction has controlled the heavily white Southern Baptist Convention (SBC) without interruption. The SBC is a thoroughly conservative force in southern politics, and the moderate faction that contested SBC elections into the 1980s has abandoned the SBC.

Former U.S. president and lifelong Southern Baptist Jimmy Carter also renounced the SBC following its adoption of resolutions prohibiting women from serving as pastors and stipulating that wives should be “graciously submissive” to their husbands. The SBC’s large numbers and lopsided Republican support easily outweigh the support that black churches can provide Democrats. Indeed, political scientist Oran Smith concluded his 1997 study *The Rise of Baptist Republicanism* by noting that the SBC and the Republican Party in the South have become virtually indistinguishable. Southern Republicans (and some Democrats), seeking political acceptance from Southern Baptists and other evangelicals, have strong incentives to take strongly conservative positions on social issues—opposing abortion, feminism, stem-cell research, pornography, gay rights, and perceived “secular humanist” influence in public life, and favoring school prayer, public Ten Commandments displays, traditional gender roles, and gay-marriage bans. Although southern religious traditions vary, the overall impact of religion in southern politics is a marked conservative (and therefore pro-Republican) influence, especially on social and moral issues, owing to the large number of Southern Baptists and other conservative Protestants in the region.

Urban Politics and Population Changes In the twentieth century, urbanization proceeded much more slowly in the South than elsewhere. But jobs and economic activity have shifted southward since World War II, and as of 2007, urban areas such as Dallas–Fort Worth, Atlanta, Charlotte, Nashville, and others are now thriving economic centers. These and similar areas have rapidly growing populations, including large numbers of migrants from nonsouthern states. These migrants were more willing to support the Republican Party than native-born white southerners were until the 1990s. In addition, those moving into southern cities were often upwardly mobile economically, making them more receptive to Republican appeals for lower taxes and less intrusive government, that is, the “low-tax, low-service” ethic. While many core cities, such as New Orleans, Richmond, Atlanta, and Memphis, have strongly Democratic black majorities, their fast-growing suburbs are heavily white and Republican. These population shifts have benefited the Republican Party, and southern “exurban” areas such as Union County, North Carolina, outside Charlotte, and suburban areas such as Cobb County, Georgia, outside Atlanta, are heavily Republican.

In some southern states, Latino populations are growing quickly. In Texas, Latinos (mostly Mexican American) make up 32 percent of the population. North Carolina and Georgia are also experiencing notable Latino immigration. Outside Florida, most Latinos migrating to southern states are Mexican American, and politically they
lean Democratic. However, Latinos’ political influence will probably lag behind their presence in the population because of language barriers for some and because some Latinos are not U.S. citizens, making them ineligible to vote. In Texas, Republican dominance rests on the heavily Republican tilt of the state’s Anglo (white) population, and Democrats will probably climb back toward competitive status only as Latinos become more politically active and vote in greater numbers.

“Law and Order”: Crime, Gun Control, and Related Issues Southernners, especially white southerners, have a pronounced conservative tilt on “law and order” issues, that is, approaches to fighting crime and drugs and punishing criminals. Most white southerners favor the death penalty, “three strikes” laws and other “get-tough” anti-crime measures, and corporal punishment in the schools, and regional policies reflect these realities. Southern states are by no means unique in allowing the death penalty; thirty-eight states, including all southern states, do. What does set the South apart is a greater willingness to convert death sentences to actual executions, and more numerous and frequent executions, as cultural psychologists Richard Nisbett and Dov Cohen (1996) show. Texas, in particular, far outstrips all other states in number of executions, with Virginia in second place. If Harris County, Texas (including Houston), were a state, it alone would rank third among the states in number of executions. The top four states in frequency of executions are Texas, Oklahoma, Virginia, and Florida, and southern states make up eight of the top ten states.

Southern states cluster near the top of all states in both the frequency of executions and the use of corporal punishment (spanking or paddling) to discipline schoolchildren. Recent initiatives to extend the death penalty to multiple-offense child molesters are concentrated in southern states. Religion probably reinforces white southern support for the death penalty, corporal punishment, and other “get tough” measures. Southern Baptist and other conservative Protestant traditions typically favor literal interpretations of the Bible and endorse harsh punishment in the criminal justice system and corporal punishment in the schools, as biblically mandated. Literal interpretations of the Bible typically endorse “an eye for an eye” doctrine in criminal justice and a “spare the rod, spoil the child” doctrine in disciplining children. Popular support for state violence and aggression is a natural byproduct of these realities.

On gun control, southerners more often oppose stricter gun control laws and support their relaxation. Nisbett and Cohen (1996) attribute greater southern opposition to gun control to the region’s “culture of honor,” which values “standing one’s ground” against an attack on one’s person or property, even if that results in killing the attacker. Southern laws on killing in self-defense are thus more lenient in southern than nonsouthern states, and southern gun control laws are more lenient.

Nationwide, Republican officials and candidates more often support the death penalty, the “war on drugs,” mandatory-minimum sentencing, and other “get tough” measures on crime policy than their Democratic counterparts do. Likewise, opposition to gun control is concentrated in the Republican Party. As such, white southerners, who constitute the center of southern conservatism, find these positions attractive, and this probably exercises a pro-Republican pull in partisan identification and voting.

Southern Military Traditions Most historians agree that southern states are home to unusually robust military traditions, reflected in southerners’ greater support for wars and willingness to fight in them. As Texas-born observer Michael Lind (2004) notes, military recruitment comes disproportionately from southern states, and southerners have been more willing to support and fight in U.S. wars overseas, including the Vietnam War, the 1991 Persian Gulf War, and the Iraq war that began in 2003. Military bases are more frequently found in southern states than elsewhere, and regional military traditions are reinforced by military academies for boys as young as ten years old. Even titles of historical studies reflect southern military traditions—for example, John Hope Franklin’s The Militant South (2002) and John Temple Graves’s The Fighting South (1985).

Politically, the South’s militaristic bent probably strengthens Republican support, as Republicans, lacking the significant contingent of peace activists that Democrats have, tend to favor more aggressive actions overseas. As Nisbett and Cohen (1996) show, the white southern “culture of honor” reinforces strong support for defense spending and military actions overseas, as well as the use of force and violence generally (i.e., the death penalty and corporal punishment).

SOUTHERN POLITICS: CAMPAIGNS, CONTINUITY, AND CHANGE

Overall, southern politics has evolved from one-party Democratic rule to two-party competition, with a Republican advantage in federal elections and some states, but competitive party politics in other states. The movement of large numbers of white southerners from the Democratic Party into the Republican Party is the overriding story of southern politics in the twenty-first century. Equally clearly, in the South, the philosophical descendants of southern Democrats before 1960 have clearly found a new political home—not in the Democratic Party but in the Republican Party. In modern southern politics,
Republican candidates typically emphasize staunchly conservative positions on national defense, social and moral, economic, racial, and “law and order” issues—a strategy designed to gain lopsided majorities among whites. Democratic candidates walk a tightrope between emphasizing such economic issues as raising the minimum wage and opposing tax cuts (popular among blacks), while at the same time dodging charges of being “liberal” (an unpopular label among whites, especially on social and moral issues). Democrats must capture a sizable share of white votes to win, but Republicans typically write off (and sometimes try to suppress) black votes. Thus, in southern politics, as of 2007, the central social cleavage remains race. That said, southern politics evidences elements of continuity with the past, as well as significant changes. The future nature and evolution of these changes will have major implications for the course of U.S. national politics.

POLITICS, URBAN

Urban politics draws upon many academic disciplines, particularly sociology, history, public policy, economics, demography, political science, urban planning, and public administration. The multidisciplinary nature of urban politics fosters both innovation and confusion, for there are many suggested definitions for the term. Intellectual differences aside, it is useful to characterize urban politics as the study of the institutions within and the governance of cities, suburbs, and other metropolitan areas. This article focuses on the study of urban institutions and governance in the United States.
As a field of study, urban politics is primarily concerned with urban political power. Specifically, urban scholars seek to define what urban power is, uncover who holds power in urban areas, and, more importantly, determine whether such power relationships are consonant with the ideals of American democracy. There are several theoretical approaches to studying urban power, the major tenets of which are summarized below.

**ELITE THEORY OF URBAN POLITICS**

Perhaps the earliest theory of urban politics is elite, or stratification theory. The elite theory of urban politics is an intellectual movement developed in the philosophies of noted political scientists and sociologists Gaetano Mosca (1858–1941), Vilfredo Pareto, Robert Michels, and Floyd Hunter, but commonly identified with C. Wright Mills and his influential book *The Power Elite* (1956). Elite theorists maintain that a few top leaders make the key decisions with little regard for popular desires. This occurs because urban areas divide naturally into distinct political classes. At the top level are the elites, most of whom are the business and financial leaders assumed to play a commanding role in urban governance. Underneath the elites is the middle class composed of the elected officials (mayors, councilmen, and the like) charged with the day-to-day operations of the city. At the bottom level are the masses, the common citizens who have limited input and influence over their government. In defense of these social divisions, elite theorists argue that elite rule is a natural consequence of democracy and a safeguard against mob rule. A major critique against the elite theory of urban politics is that it paints a negative picture of urban democracy, for policies are made independently of public opinions, elections are perfunctory, elites are ultimately self-interested, and corruption in government is inevitable.

**PLURALIST THEORY**

In response to the criticisms of elite theory came the pluralist, or interest group, approach to urban politics, a scholarly tradition influenced heavily by the works of Robert Dahl, Charles Lindblom, and David Truman. Rejecting the idea that democracy is a sham, pluralists argue instead that urban governments are open and democratic, that citizens have free will, and that elections are the ultimate guarantee of democracy. Once the dominant paradigm of urban power, pluralists argue that societies consist of numerous institutions and organizations, each having diverse cultural, religious, economic, racial, and ethnic interests. Political resources divide among these different groups, and policies are made by group conflict and collective bargaining. Such group competition allows dif-

ferent interests the chance to influence the outcomes of government, which ultimately furthers urban democracy. While it is an improvement over elite theory, some common critiques against pluralism are that it underestimates the strength of elites and fails to account for the interests of individuals who are systematically excluded from the political process (for example the poor, racial/ethnic minorities, and so on).

REGIME (OR COALITION) THEORY
An increasingly popular theoretical perspective is the regime (or coalition) theory of urban politics. Borrowing from the intuitions gained from the literature on foreign policy, regime theorists suggest that urban power is indirect and informal and realized through coalitions (regimes) between government and nongovernment partners. One of the more widely cited books in regime theory is Clarence N. Stone’s *Regime Politics: Governing Atlanta, 1946–1988* (1989). Regime theorists contend that understanding urban governance requires examining the composition of political coalitions and the manner in which members of these coalitions are accommodated. A recurring argument among regime theorists is that power is a “social production,” something that occurs when different interests unite to achieve common purposes. Decision-makers have relative autonomy, but they have to create a “capacity” to govern to be successful. To do so, leaders need to combine forces with private agencies to induce cooperation among people with access to institutional resources. Despite its widespread appeal, regime theory has its share of critics. A common argument against regime theory is that it does not adequately explain why regimes form, how they maintain themselves, or why they change.

Much of the research on American political power focuses on national trends. This is unfortunate because large-scale analyses depend on the insight gained from state, local, and municipal-level research. To borrow the phrasing of former Speaker of the House, Thomas “Tip” O’Neill (1912–1994), the study of urban politics reminds social scientists that “all politics is local.”

POLL, EXIT
SEE Exit Poll.

POLL TAX
Poll taxes, also known as head taxes, soul taxes, or capitation taxes, are taxes that are levied upon individuals, rather than on income or property. Economists are divided over the efficacy of the poll tax. Some economists argue that...
the poll tax is a regressive tax, while others argue it is an effective mechanism for ensuring that public expenditures more closely reflect public demand. Although poll taxes are technically revenue measures, their enactment can have political implications.

Poll taxes have been part of recorded human history with Ptolemaic Egypt leaving the first records of these taxes. The poll tax has been used intermittently in European countries such as Britain, Prussia, and Russia since the Middle Ages. It was also used in some areas of the Ottoman Empire. Some European countries such as Britain and France also imposed poll taxes (also known as hut taxes) on their colonies in Africa and Asia.

In the United States poll taxes date back to its colonial era. In some jurisdictions poll taxes were linked to suffrage, while in other jurisdictions the poll tax was simply another form of revenue. In the post–Civil War era, the poll tax emerged as one of the techniques used by southern whites to disenfranchise African Americans. Along with other disenfranchising techniques, the poll tax was designed to be an instrument that could evade the reach of the Fifteenth Amendment (stating that no state may deny or abridge the right of citizens to vote on account of race, color, or previous condition of servitude; citizens may not be prevented from voting due to race) and any other federal intervention. In order to be eligible to vote, an individual had to pay a poll tax. In some cases the poll tax had to be paid almost a year in advance of the election, and in other cases the tax had to be paid for a certain period of years. In the aftermath of the political upheaval of populism (a social movement of southern and western farmers and workers) in the late 1890s, the poll tax also became a device used by the southern political elite to decrease the influence of poor whites on southern politics. By 1908, all of the southern states had enacted a poll tax. By the 1930s, as a result of the poll tax, it was estimated that white electoral participation dropped to less than a third of the total voting age population.

The administration of poll taxes varied across the states. Some states added the bill automatically to other tax bills, while other states required individuals to make a separate payment. Some states required annual payments, while others also included cumulative charges as well. These back taxes, coupled with the low cash income of many southerners, made voting an expensive proposition, thereby further depressing voter registration. Varied enforcement or non-enforcement of poll tax payments and the varied provisions across the states made the impact of poll taxes on a particular state’s rate of electoral participation hard to calculate. A number of states included exemptions based on age or veteran status. What was easier to calculate was the fiscal impact of poll taxes. Although supporters of the poll tax claimed that the taxes provided an important revenue source for local school systems, most analyses showed that only a minute fraction of school funds derived from poll tax revenues.

Although most African American leaders opposed the poll tax, leaders and organizations such as the National Association for the Advancement of Colored People (NAACP), for example, did not actively pursue poll tax reform until the 1930s. In addition to African Americans, southern women activists increasingly viewed the poll tax as a gender and class issue that undercut the promise of the Nineteenth Amendment (guaranteeing all American women the right to vote). Given the overall low incomes of white families, gender roles ensured that if a choice had to be made between paying the poll tax to ensure the right of a male to vote versus a female, the male’s right to vote would invariably win out. V. O. Key Jr. (1908–1963) and his student Frederic Ogden were two of the first political scientists to systematically study the effect of the poll tax on electoral participation in the late 1940s and early 1950s. The political scientists’ conclusion that the poll tax affected more whites than blacks was weakened as they did not consider the cumulative effects of the poll tax and other disenfranchising techniques on African Americans, nor did they consider the effects of this tax on the electoral participation of women.

By the late 1930s, with the support of President Franklin D. Roosevelt (1882–1945) and First Lady Eleanor Roosevelt (1884–1962), a variety of groups such as the Southern Conference on Human Welfare, the American Civil Liberties Union, and the NAACP, allied with two newly formed organizations, the National Committee to Abolish the Poll Tax and the Southern Electoral Reform League, to press for congressional enactment of a poll-tax bill. As a result of this mobilization as well as other developments, the poll tax emerged as an important national civil rights issue in the pre-Brown v. Board of Education (1954) era. By the end of the 1940s, the House of Representatives would ultimately pass five anti–poll tax bills, which in turn were repeatedly filibustered in the Senate by southern Democrats.

Concurrent with legislative attempts to attack the poll tax, opponents of the tax also turned to the courts where they encountered little encouragement. For example, in 1937 the Supreme Court indicated in Breedlove v. Suttles 302 U.S. 277 that it was not willing to see the poll tax as a suffrage test. Another important case was decided in 1941. Pirtle v. Brown (118 F.2d 218 [1941]) affirmed the right of states to set voter qualifications.

Despite these setbacks at the congressional and judicial level, poll tax reform achieved some success at the state level. By 1953 six out of the eleven southern states had abolished the poll tax. North Carolina abolished the tax in 1920; Louisiana in 1934; Florida in 1937; Georgia
Polling

in 1947; Tennessee in 1951, and South Carolina in 1952. Of the remaining five states, two states (Alabama and Arkansas) reformed their poll taxes by decreasing the cumulative feature and the amount of the tax, and three states (Mississippi, Texas, and Virginia) failed in their attempts to repeal or amend the tax.

Nevertheless, as the civil rights movement unfolded the poll tax became less of an immediate issue. Its applicability to federal elections was prohibited in 1964 with the ratification of the Twenty-fourth Amendment, which stated: "The right of citizens of the United States to vote in any primary or other election for President or Vice President, for electors for President or Vice President, or for Senators or Representative in Congress, shall not be denied or abridged by the United States or any State by reason of failure to pay any poll tax or other tax." Despite this amendment, some states still tried to use poll taxes. A later court case, Harper v. Virginia Board of Elections 383 U.S. 663 (1966) extended the reach of the Twenty-fourth Amendment to state elections.

In Europe, Great Britain had enacted short-lived poll taxes in 1379 and in 1641. More recently, the British government during the administration of Prime Minister Margaret Thatcher (b. 1925) tried to enact a poll tax in 1990 as a means of controlling local government expenditures. Although initially successfully implemented in Scotland in 1989, the administration's attempt to enact a poll tax in England met with stiff resistance by a broad range of groups. This resistance ultimately culminated in protests and riots in March 1990. The poll tax riots, as well as other factors, led to the end of the Thatcher administration. Despite the resistance, the poll tax survived under slightly different form as the Community Charge or Council Tax.

POLLING

Polling involves gathering information by asking people to report their beliefs, attitudes, and behaviors. First, it is one of the most widely used techniques in social science research, of particular interest to political scientists, who use surveys such as the University of Michigan's American National Election Studies to analyze relationships between political attitudes and other attitudes, voting behavior, and participation. Second, polling has numerous applications in business through market research studies to assess customer satisfaction, identify new markets, and identify new prospective customers. Third, polling is applied in campaign politics. Party and campaign organizations frequently use tracking polls to identify candidates' standing, strengths, and weaknesses during campaigns. Fourth, polling is used in policy analysis and program evaluation. Nonprofit organizations and local, state, and national governments are often interested in their clients' opinions of their services and programs—this information is useful in program assessment and evaluation. The political scientists Barbara Bardes and Robert Oldendick (2007) provide an especially extensive discussion on the uses of opinion polls. Throughout this entry, the terms poll and survey are used interchangeably.

THE DEVELOPMENT OF SCIENTIFIC POLLING TECHNIQUES

During the twentieth century polling techniques became much more scientific, spurred in part by failed efforts by pollsters to predict presidential election results in 1936 and 1948. As noted by the political scientists Robert Erikson and Kent Tedin (2005), in 1936 a straw poll from Literary Digest magazine predicted that Republican candidate Alf Landon (1887–1987) would defeat Democratic president Franklin D. Roosevelt (1882–1945). The poll was off by nearly 20 percentage points, as Roosevelt won handily. Responses to this survey heavily overrepresented the wealthiest (and heavily Republican) groups of Americans. Respondents were drawn from automobile registration lists and telephone directories, but during the Great Depression, most automobile and telephone owners were wealthy. In 1948 preelection polls predicted that Republican candidate Thomas Dewey (1902–1971) would defeat Democratic president Harry S. Truman (1884–1972). However, this poll also relied on flawed sampling that overrepresented the better-off. As a result the 1948 poll overrepresented Republicans. Chastened by
Polling

these polling mistakes and seeking to avoid future ones, pollsters were spurred to develop scientific polling methods.

ELEMENTS OF SCIENTIFIC POLLING

Scientific polls have several major characteristics that distinguish them from nonscientific surveys. First and foremost, scientific polls use samples of respondents that mirror the larger population under study. In a large, diverse nation like the United States, interviewing all American adults in a survey is impractical and impossible owing to prohibitive costs, resource constraints, and time limits. Thus pollsters rely on adult samples, selected randomly, such that all individuals have an equal chance of being included in the sample. This random sampling process usually yields a sample that closely reflects the characteristics of the larger population—that is, the sample is representative of the larger population. Statistically samples are most likely to be representative when random sampling methods are used and sample size—that is, the number of completed surveys—approaches or exceeds one thousand, with larger sample sizes producing better results.

Second, scientific polls use survey questions that are carefully constructed, clear and nonconfusing, and free of biased or "leading" language. Confusing language can sometimes produce major polling surprises. A 1993 Gallup Poll sponsored by the U.S. Holocaust Memorial Museum in Washington, D.C., revealed that 22 percent of Americans either were unsure of or doubted the Nazi extermination of the Jews during the Holocaust. This stunning finding was soon called into question, however. Close examination of the poll questions revealed a confusing double negative in the survey question. Follow-up polling using a revised question showed more comforting results: Only 1 percent of Americans actively doubted the Holocaust had happened, with an additional 8 percent unsure. The sociologists Howard Schuman and Stanley Presser ([1981] 1996) offer extensive evidence of the impact of question wording on survey results. Their and others’ research shows that tone of wording, question ordering, question context (or lack thereof), and differences in response formats (i.e., a three-point scale versus a seven-point scale) all can significantly affect survey responses. How a question is asked, then, definitely shapes the answers received.

A third element of scientific polling is accurate and thorough reporting of results. Scientific surveys include a statement of how the poll was conducted and what the limitations of the survey are. Such a disclosure statement should include how many completed surveys there are; interviewing techniques used (in-person, telephone, or mail questionnaires); how respondents were selected (random sampling is best); the survey’s margin of error and confidence level, two numbers indicating how well results will likely extend to the general population; any additional survey techniques, such as weighting of respondents, use of variations in question wording, or interviewer characteristics; and limitations of the survey. Above all else, scientific polling means that the pollster seeks to accurately measure attitudes, opinions, and behaviors, not influence them.

Some surveys are not scientific, for varying reasons. Some news media, such as MSNBC, have Web sites where viewers can answer an online survey. These are not scientific surveys as they lack the key ingredient of random sampling. Scientific polls do not allow people to self select into completing the survey. Similarly mail-in surveys found in some magazines and call-in polls used on some television shows are unscientific. Other “surveys” sponsored by political parties, campaigns, and interest groups are unscientific because they frequently use “loaded” questions that (usually not subtly) encourage some responses over others. At best these qualify as “pseudo-polls” because their objective is not to accurately measure opinion but to arouse support for the sponsoring party or group or anger at political opponents. A 1993 TV Guide survey sponsored by Ross Perot contained clearly loaded questions, including “Should laws be passed to eliminate all possibilities of special interests giving huge sums of money to candidates?” Such loaded questions provide virtually no meaningful information, but they do provide examples of how some surveys fall well short of scientific standards for measuring public opinion.

POLLING IS NOT PERFECT: THE PROBLEM OF SELF-CENSORSHIP

An additional limitation of polling is that some respondents face questions they prefer not to answer, resulting in self-censorship, which can take several forms. Someone contacted by a pollster may refuse to answer some questions, refuse the entire survey, or give insincere answers. Insincere responses are especially likely on sensitive subjects, such as past drug use, sexual activity, or racial attitudes, where some respondents answer falsely to give more “socially desirable” responses. The sociologist Eduardo Bonilla-Silva (2006) studied white Americans’ discourse on racial issues and found a prevalent “color blind racism” in which many whites deny holding racist attitudes, contending that racism is “a thing of the past” and that race does not impact their attitudes and behaviors. This phenomenon perpetuates white dominance by denying continuing racial discrimination, revealing negative racial stereotypes, such as attitudes that minorities (especially blacks) tend to be lazy, violent, and lacking in self-restraint and attributing racial-group differences in
income, housing, education, crime, and other areas to individual choices or market forces that have nothing to do with race. The political scientist Martin Gilens (1999) found that white Americans’ opposition to welfare is frequently driven by racial stereotypes that welfare recipients are usually black and that blacks are often lazy and shiftless, preferring to collect handouts rather than work.

The political scientists Jon Hurwitz and Mark Peffley (1997) found that white attitudes favoring punitive anti-crime policies are often driven by stereotypes of blacks as violent and disposed to criminal acts. Similarly the political scientists Joe Soss, Laura Langbein, and Alan Metelko (2003) studied white Americans’ attitudes toward the death penalty. They found that racial prejudices were by far the single strongest explanation for whites’ death penalty attitudes, especially in areas where blacks comprise a larger share of the population. In all these cases, white attitudes on issues that appear non-race-related on the surface are suffused with racial stereotypes. But few whites in the early twenty-first century would admit they hold negative racial attitudes (“I’m not racist”) or that those attitudes influence policy preferences. Social scientists must often use creative methods, such as unobtrusive survey questions on racial attitudes or experiments that vary question wording within surveys, to demonstrate the racial components underlying these attitudes.

THE IMPORTANCE OF POLLING IN POLITICAL SCIENCE RESEARCH

Polling has a central place in political science research. Academic survey research centers exist at major universities, such as the University of Chicago, the University of Michigan, and the University of California at Berkeley; these frequently sponsor nationwide scientific surveys. More survey research centers conduct further polling in many states. Collectively the polling conducted by these centers yields invaluable data for political scientists. For example, a researcher wishing to examine how racial stereotypes or beliefs in biblical inerrancy impact voting can use data from the University of Michigan’s American National Election Studies, which measure these and many other social science variables. Statewide surveys, such as the Arkansas Poll sponsored by the University of Arkansas, or regional surveys, such as the Southern Focus Poll sponsored by the University of North Carolina at Chapel Hill, provide more data that political scientists find useful in researching attitudes in a state or region of the country. Although polling outside the United States presents many additional challenges, there is increasing demand for cross-national polling data, including that from Middle Eastern, Asian, and African nations. The World Values Survey, sponsored by multiple universities worldwide, has provided polling data from more than eighty nations since 1981. These data are opening new avenues for political scientists to better understand public opinion not just in the United States but worldwide.

POLLS, OPINION

Opinion polling is a method of analysis for drawing inferences about the attitudes or behaviors of a population by studying a random sample of persons from that population. Nonrandom surveys are sometimes used by social scientists for theory building, but only random samples can produce valid estimates of population traits. Since social scientists are typically interested in population traits, and since few other methods are as useful for studying population traits at the level of individuals, opinion polling with random samples has become one of the most common methods of data collection in the social sciences. Space does not allow a full treatment of this topic internationally and across the social sciences, but detailing the early adoption and continued use of opinion polls for political science research in the United States provides a useful introduction to the reasons why opinion polling remains such an important tool for the social sciences.
OPINION POLLS IN POLITICAL SCIENCE

Political scientists have long studied elections and public opinion, but before the 1940s they tended to emphasize how elections and public opinion should work in theory more than how they actually did work in practice. In part this emphasis reflected the scholarly paradigm of this period, which saw the core questions of democratic politics residing in the institutions, processes, and outcomes of political systems more than in the ways ordinary citizens made sense of them. But this emphasis was also encouraged by limitations in early methods of social analysis, which often forced scholars to speculate about factors influencing election outcomes because they lacked systematic evidence for studying many questions of interest. During this period, the best forms of voting data available to political scientists were aggregate election results that could be compared across voting districts or geographic areas, but such data had little to say about the reasons why individuals decided to participate in elections or why they supported particular candidates.

The development of random sampling surveys in the 1930s had a lasting impact on the ways that political scientists studied elections and public opinion. Nonrandom straw polls that included anywhere from dozens to millions of citizens had been used to predict elections and describe public opinion since the 1820s, but these proved to be invalid methods of social inquiry. Their results could not be generalized to larger populations because the people who answered such polls were not a random cross-section of society. The demise of the straw poll came in the presidential election of 1936, when the Literary Digest magazine incorrectly predicted a Republican win over Democratic incumbent Franklin D. Roosevelt (1882–1945). George Gallup’s (1901–1984) new random sample survey correctly predicted a Roosevelt win, and he demonstrated that the Digest Poll’s biased sample was the source of its inaccuracy.

The success of random sampling at predicting elections quickly encouraged its adoption by political scientists, and the 1944 publication of The People’s Choice—the first systematic analysis of American voting behavior to use modern opinion polls—marked a major turning point in political science research. The transformation of this research tradition is widely considered to have been completed with the 1960 publication of The American Voter, which became a cornerstone of political behavior research in America. By this time the opinion poll—particularly the American National Election Study—had become the standard tool for political science research on mass opinion and voting behavior, as it remains a half century later.

The rapid adoption of polling came during a transitional period in political science known as the behavioral revolution, and stems in part from two parallel developments that were occurring at the same time. The first is the rise of methodological individualism as a critique of the dominant style of inquiry common to social science scholarship before the 1940s, which tended to explain any particular social phenomenon as a product of other social phenomena. For example, an election outcome might be explained as resulting from the state of the national economy. Methodological individualism held to the contrary that any social phenomenon was a collective product of individual-level behavior. For this school of thought, explaining election outcomes as a product of the economy requires understanding how economic factors influence the choices made by individual voters. Because opinion polls could measure not only political behavior but also the underlying attitudes that precede and shape such behavior, polls fit squarely with the tenets of methodological individualism and with the new paradigm of scholarship championed by behavioral researchers. The second development was the rapid growth of the science of statistics during the first half of the twentieth century. Polls not only provided information about the attitudes and behaviors of individuals, but when sampled using the new random probability methods they produced findings that could be generalized to entire populations. It was this unique combination of developments, arriving as the behavioral revolution was getting underway, that quickly transformed the opinion survey into the standard method for opinion research in the United States.

THE STATISTICAL LOGIC OF OPINION POLLING

The ability to generalize survey findings from a sample of 1,500 respondents to a population of millions comes from strict adherence to the statistical principles of random probability sampling. Researchers often want to study the attitudes or behaviors of a population, such as adults in the United States. Although they might prefer to include every member of the population in a survey, conducting a census for any but the smallest of populations is prohibitively expensive and fraught with difficulties. The solution offered by random probability sampling is a compromise. If a small subset of the population is selected at random to take the survey, then the central tendencies of that sample—such as the percentages of people holding various opinions—will tend to be quite similar to those of the population from which they were drawn. The compromise comes in how closely the sample estimates are likely to match the true characteristics of the population. Random sampling allows for a small amount of error between the mix of answers given by the sample and those that would be revealed by a census of the population, and also allows for the possibility that once in a while the sam-
people may have quite different characteristics from the population.

Because random sampling allows researchers to accurately determine the probability that both kinds of error will occur in a given sample, they can assign a level of confidence to the likelihood that the sample results approximate the population’s actual characteristics. The probability estimate for the first type of error is called the margin of error, defined as the range of values around a sample estimate in which the true population value is likely to be found. The size of the margin of error is determined by the number of persons included in the sample, with larger samples allowing more precise estimates. The margin of error for a sample of one thousand persons is plus or minus three percentage points, meaning that the proportion of respondents in the sample holding a particular opinion should be within three percentage points either way of the true population value. The probability estimate for the second type of error is called the confidence level, which is the likelihood that a population’s true value falls within the range given by the sample's margin of error. Typically, random samples are drawn with a 95 percent confidence level, meaning that the population’s true value should fall within the sample’s margin of error ninety-five times out of one hundred.

These error estimates presume that each individual in a population has an equal and random chance of being selected, but other types of error can also influence poll results. Any violation of equal and random selection may produce sampling errors that can bias survey estimates away from the population's true value. Nonresponse errors can occur when persons selected to be in the sample are never contacted, decline to be interviewed, or refuse to answer particular questions. Measurement errors can be introduced by the wording of questions and the order in which they are asked. For example, answers obtained by asking respondents to select from a list of pre-determined responses—using what are called “forced-choice” questions—can produce different estimates of public opinion than answers obtained by recording the verbatim responses provided by respondents using “open-ended” questions. Errors of conceptual validity can occur when a question fails to adequately measure the concept of interest to survey researchers. These other types of error are not taken into account by the sample’s margin of error or confidence level.

POLLS AND THE STUDY OF PUBLIC OPINION

Opinion polls are used by political scientists for four main purposes. First, polls are used to measure and predict political behavior. Pre- and postelection surveys help political scientists understand why citizens support particular candidates or parties. Election-day exit polls provide insights into the demographic and social characteristics of voters. Second, polls are used to chart trends in behavior and attitudes over time. Tracking polls, which consist of small samples taken every few days during the course of an election campaign, clarify how citizens respond in the short term to campaign activities. Trend analyses pose the same questions to different samples every few months or years to study long-term changes in the attitudes and behaviors of a population. Third, polls are widely used for correlational analysis, which examines how attitudes and behaviors are related to one another at the individual level. Fourth, polls are used to conduct general population experiments, where samples are divided into treatment and control groups to produce experimental findings. Unlike traditional laboratory experiments, the findings from survey experiments can be generalized to populations, which makes this combination of methods increasingly appealing to social scientists.

Polling has helped political scientists understand public opinion processes, but it also has changed the ways that political scientists think about public opinion. Up until the middle of the twentieth century, a sociological paradigm emphasizing the activity of organized groups informed the mainstream of opinion research in the social sciences. Before the behavioral revolution, the phenomenon of public opinion tended to be associated with action or barriers to action rather than merely with a potential to act. In contrast, newer psychological interpretations of public opinion associated with the behavioral revolution and informed by survey research have tended to view attitudes rather than actions as the primary phenomenon of interest. Likewise, while the earlier sociological conceptions of public opinion were concerned with action conducted by interested groups rather than the population as a whole, the method of random sampling has cultivated a perspective that views public opinion as an attribute of unorganized masses or entire societies. As a byproduct of this paradigm shift, the rise of polling has encouraged political scientists to neglect sociological and philosophical dimensions of public opinion research that once had been vibrant areas of social inquiry.

Pollsters

Pollsters are professionals dedicated to working with polls, which are sample surveys designed to uncover information about a defined population through questioning a representative sample. Scientific polling developed in the wake of the predictive failure of prescientific methods that used nonrepresentative samples. The most famous early pollsters began work in the 1930s and took part in government efforts to mobilize citizens in the United States during the Great Depression, the New Deal, and World War II. Soon after the war they generally emerged as heads of their own polling organizations, notably George Gallup (1901–1984), Elmo Roper, and Archibald Crossley. These names became synonymous with polling, and they not only sold clients on polling’s value but also argued for and succeeded in giving polling results a prominent place in democratic politics. Gallup especially popularized polling’s roll in governance, and he wrote several books on the subject, including The Pulse of Democracy: The Public-Opinion and How It Works. He also was a groundbreaker in the practice of regularly releasing poll results that revealed feelings about contemporary political issues. At the same time many pollsters entered academics, particularly Angus Campbell, Donald Stokes, Phillip Converse, and Warren Miller, who founded the Center for Political Studies. That group created American voting studies and the National Election Studies, a poll that offers data on voting, public opinion, and political participation and that continues in the early twenty-first century. A similar effort started later at the National Opinion Research Center, whose General Social Survey also remains in use in the early twenty-first century.

Modern pollsters play an important but somewhat underexamined social, political, and economic role in the development of information about large groups in society, especially polls directed at entire nations or states. While the number of practicing pollsters is not large, they collectively do many polls each year, often several simultaneously. Each poll can be an independent project requiring customization of two steps, creating a sample and conducting interviews. To create the sample, a population must be identified, and then chance is used to select a statistically representative subset. The interview requires developing a questionnaire with an overall theme as well as formulating specific questions. Pollsters also repeat certain questions in order to publicize specific public attitudes that have become associated with their organizations. The Gallup and Roper organizations are known, for instance, to frequently poll on citizens’ approval of the U.S. president.

Pollsters tend to be budget sensitive, as they must maintain a staff that includes statisticians, interviewers, analysts, and writers as well as pay other administrative costs; thus their tasks involve satisfying clients’ needs. Although they overlap, pollsters can be categorized by clientele. In broad strokes, clients are media organizations, businesses, or other private entities or academic enterprises. Media pollsters tend to work directly or indirectly with reporters and editors, generally part of the news department, to produce newsworthy tidbits about public attitudes for a wider audience. These pollsters tend to have journalistic goals and tailor efforts to supporting their organization’s mission and specific projects. Increasingly media pollsters aid in the production of lifestyle pieces, like polls concerning parents’ attitudes toward college.

Private pollsters work for specific clients ranging from large businesses and nonprofit organizations to political groups, including individual candidates. They use polls to uncover information clients consider valuable. Such information may help design public communication, for example, marketing a new product; assess performance by surveying customers or employees; and develop new ideas by surveying particular demographic categories. Pollsters have taken on increasing responsibility in political campaigns as well, performing similar functions but in the intense campaign environment. In assisting candidates with elections, pollsters have become central advisers, helping to assess candidates and issues, drafting advertisements, and even structuring policy proposals. In so doing pollsters play a prominent role in governance.

Within scholarly communities pollsters are spread widely in the social sciences, working for academic institutions to further knowledge about human thoughts and
behavior. In addition to political science, pollsters work in sociology, communication, psychology, public health, and economics pursuing studies relevant to each discipline. The well-known studies of consumer confidence produced by pollsters at the University of Michigan, for instance, help forecast future business conditions. Likewise the Euro barometer has become widely used by scholars to compare attitudes across countries. Though most pollsters working in the early twenty-first century are nonacademics, much of their training came from universities, and academics often take advantage of data produced by nonacademic polls.

POLLUTION

Pollution is the contamination of the natural environment by one or more substances or practices. Most pollution is an externality—an unintended by-product—of the use of energy and other products that have become central to industrial society. As a consequence, pollution is very difficult to eliminate, because doing so requires change in people’s use of these central products and systems. The automobile, for example, is the single most important component of the transportation systems of Western industrial economies, yet it is also a major source of air and water pollution, toxic wastes, and noise.

Pollution of vital “common resources” such as air and water is an especially challenging problem. Because these resources are owned by society as a whole and cannot be divided among individuals, their use is often regarded as being free. The benefits to the individual of using common resources (for instance, disposing of chemical wastes by dumping them in a river) are frequently tangible and immediate (in this case, avoiding the expense of proper disposal), whereas the costs of such use are typically long-term, intangible, and paid by the community as a whole (in the form of polluted water). Thus, it appears to be rational for an individual to make maximum use of common resources, even at the risk of their overuse and eventual destruction.

The single most important cause of pollution, especially in industrial societies, is the use of fossil fuels in cars, industries, and homes. Fossil fuels include petroleum, coal, natural gas, and uranium. Major forms of air pollution, such as global warming, acid rain, depletion of the stratospheric ozone layer, and airborne toxic chemicals, all result at least in part from the incomplete burning of fossil fuels. The main piece of legislation governing air pollution in the United States is the Clean Air Act Amendments (CAA), first passed in 1970 and amended several times, most notably in 1990. The guiding principle of the CAA was to require that industrial expansion incorporate efforts to reduce air pollution. Market-based incentives have been added to the CAAA, particularly in the 1990 acid rain title, and are considered by many economists and policymakers to be more effective and more politically palatable than the traditional command-and-control approach to pollution control.

Fossil fuels cause water pollution as well, in the form of oil spills, industrial emissions, and acid rain. Congress passed the Federal Water Pollution Control Act in 1972 to restore the integrity of U.S. waters, and the Safe Drinking Water Act in 1974, giving the Environmental Protection Agency (EPA) the power to set standards for drinking water quality, which are implemented by the states. These legislative initiatives have had demonstrable though partial success, though many aspects of water pollution control, such as the protection of wetlands, remain highly controversial and limited.

Toxic chemical wastes became an important issue in environmental policy soon after the tragedy of Love Canal, an area of Niagara Falls, New York, where the Hooker Chemical Company transferred ownership of some land to the local government for the building of a school. Hooker Chemical had previously dumped massive quantities of hazardous chemicals in the area, and families living nearby began to be alarmed by an unusually high incidence of illnesses and birth defects. The Superfund program, passed in 1980 and reauthorized in 1986, has been the most far-reaching and expensive legislative effort to clean up toxic wastes on land that has been abandoned by its owners. The program has a significant number of drawbacks, however, including the facts that a substantial amount of Superfund money has been spent on lawsuits rather than on remediation of sites, the number of sites cleaned up is a small proportion of the total proposed for...
Another serious pollution problem stems from the use of artificial radioactivity for the development and testing of nuclear weapons as well as for the production of electrical power. Although nuclear power plants do not emit the same levels of air pollutants that coal and oil-fired power plants do, radioactive substances such as uranium and plutonium are powerful poisons. Meltdowns and near-meltdowns of nuclear plants (such as the Chernobyl disaster in 1986 in Ukraine) have sharply discouraged the use of nuclear power in the United States, as has the inability to create completely inviolable, long-term storage for nuclear wastes.

In addition, pollution problems and loss of habitats have contributed to the extinction of many species of plants and animals. The Endangered Species Act (ESA) of 1973 established a series of regulations to protect endangered and threatened species and the ecosystems on which they depend. The ESA generally has been considered to be successful; conflicts between requirements of the ESA and projects proposed by developers were effectively resolved during most of the act’s existence. However, in recent years the property rights movement has taken strong exception to the continued enforcement of the ESA.

Other forms of pollution are less commonly recognized. One is indoor air pollution. As people work to bring down the high cost of heating and cooling by weatherproofing their homes, the atmosphere in these more airtight homes is more easily contaminated by pollutants such as cigarette smoke and toxins given off by carpeting, paneling, and household chemicals. Another, less commonly recognized form is light pollution: the excessive use of artificial light that brightens the dark sky, interfering with the work of amateur astronomers and harming nocturnal wildlife and other ecosystems. A third, noise pollution, refers to excessive noise levels, typically in urban and industrial areas, which not only disrupt people’s lives and work but also raise blood pressure and stress levels, cause hearing loss, and interfere with the natural feeding, breeding, and migration cycles of animals.

Desertification—the encroachment of desert-like conditions into semidesert land—has been identified in large areas of Asia, Africa, and North America. The use of wood rather than oil or coal for fuel leads people in many developing nations to cut trees on a large scale; this often leads to disastrous flooding because tree roots can no longer hold topsoil in place when the rainy season comes. The burning of agricultural lands to clear dead vegetation, a common practice among farmers in many nations, can cause clouds of soot to move across neighboring nations.

Many of the most common forms of pollution have substantial economic impacts. Increases in air pollutants such as sulfur dioxide and urban ozone affect human health, causing or worsening conditions such as asthma, emphysema, and lung cancer. The resulting costs of medical treatment and shortened life expectancy affect a nation’s productivity. Those who usually suffer are often the most vulnerable members of society: the elderly, the sick, the poor, and the very young. The environmental justice movement charges that the burden of pollution-caused health problems tends to fall most heavily on disadvantaged groups because these groups are least able to mobilize politically to demand pollution control. In more affluent areas, NIMBY (“not in my backyard”) groups often have been successful at preventing the siting of incinerators, waste dumps, and other environmental hazards that can undermine property values in their neighborhoods.

Cleaning up pollution is very expensive as well. The EPA estimated that the provisions of the CAAA have cost $523 billion to implement between 1970 and 1990 (U.S. Environmental Protection Agency 1997). Some economists and political leaders regard this as unproductive spending, in that these expenditures do not help the businesses spending the money produce more goods. According to the 1997 EPA study, however, during this time period the application of the CAAA saved 205,000 American lives and provided between $6 and $50 trillion in economic benefits. Spending on pollution control goes in part to fund the manufacture of pollution control equipment, which adds to economic growth.

Pollution levels in the United States generally have improved as a result of the pollution-control policies of the past thirty years. Recycling and “precycling” (developing methods of manufacture that produce smaller amounts of waste) have reduced the production of solid wastes in many communities. The amount of lead (a neurotoxin) recorded in the air and in human blood samples is substantially down from 1970 levels, in large part because of the removal of lead from gasoline, due to the CAAA. Some international agreements have been effective, such as the Montreal Protocol (1987), which appears to have stabilized the problem of depletion of the stratospheric ozone layer. The improvement has been uneven, however. Urban ozone levels remain a substantial problem for most big cities in the United States. Global warming (Gore 2006) poses an extremely serious risk to the planet, and pollution problems are worsening rapidly in many industrializing nations, such as China and India.

POLLUTION, AIR
The economy extracts natural resources from the environment to be used as inputs in production processes (the source function of the environment). The output of these production processes may be either produced inputs for yet other production processes or final products to be directly consumed. Yet these produced inputs and final products are not the entirety of the output; there are also residual by-products of these processes (waste).

Just as the economy extracts natural resources from the environment, the economy in turn dumps many residual by-products, or waste, back into the environment (the sink function of the environment). There is waste at each stage of the economic process: waste from extracting and refining natural resources, waste emanating from production processes, waste in the marketing of products, and waste in the sphere of consumption. Wastes may be solid, airborne, or waterborne. Air pollution describes airborne wastes that can harm the environment and human health due to their accumulation in the atmosphere, their concentration geo-spatially, and/or their synergistic effects when combining with other wastes.

There is an interesting relationship between the total natural resources utilized and the total waste produced by the economy. That is, they are ultimately equivalent. This is due to the first law of thermodynamics, which states that matter-energy can neither be created nor destroyed; only the form of matter-energy can change. Of course, it is more complicated than a simple equality. Natural resources are frozen in the form of capital goods during the depreciation process (and capital goods from previous periods are at differing stages in the depreciation process), and there is a time element in the consumption of many final products as well. At a fundamental level, however, the equality holds.

RESOURCES AND POLLUTION
Some wastes are recyclable or reusable and others are not. The fact that all waste is not recyclable or reusable is due to the second law of thermodynamics, which states that any utilization of matter-energy decreases the total available matter-energy. In other words, some of the forms into which matter-energy is transformed can no longer be accessed. This is also known as the entropy law, and put differently means that not all the forms into which matter and energy are transformed are recyclable or reusable. That waste which is not recycled or reused is dumped into the environment.

The environment has an assimilative capacity, which is the ability of the environment to transform waste into harmless (or even beneficial) forms. This assimilative capacity, however, is not infinite. Waste at some level is not only incapable of being assimilated, but will damage or even destroy the assimilative capacity itself.

It is not simply the level of homogeneous waste in relation to the assimilative capacity that needs to be considered, but additionally what specific types of waste are being emitted. Some types of waste (e.g., mercury) are not assimilable in any quantity, and at some stock level can result in various detrimental effects, including damage to the assimilative capacity itself. In addition, it is not sufficient to simply look at each type of waste and the quantity of it emitted in isolation, one must consider also its synergistic effects. The combinations of different forms of waste have effects that are more damaging than the sum of the component waste products independent of one another. A classic case here is sulfur dioxide and nitric oxide resulting in acid precipitation (acid rain, fog, and snow).

The qualities and quantities of waste globally along with spatial considerations concerning the local concentration of wastes are crucial. And it is not simply the case that the assimilative capacity detoxifies or degrades waste instantaneously, or even within some set time period. There are accumulation effects that have to be dealt with. So in assessing the ability of the assimilative capacity to deal with industrial and other waste, combination effects, concentration effects, and cumulation effects all need to be carefully considered.

Furthermore, nothing guarantees that all waste that is capable of being recycled or reused is being recycled or reused. All waste, whether recyclable or not, which is dumped into the environment, may impact on the assimilative capacity. Therefore, when considering the quantities and qualities of wastes confronting the assimilative capacity, only those residuals may be exempted that are actually recycled. Generally speaking, the technologies do not yet exist to capture and recycle airborne emissions.
EVOLUTION OF AIR POLLUTION REGULATION

In the United States, early air pollution laws were enacted locally in Chicago and Cincinnati. These were smoke control laws that addressed only smoke emissions from coal burning. Before 1948, there was almost no real government intervention in the environment, which means that there was, by default, a market approach to natural resource use and environmental protection.

An early recorded disaster resulting from air pollution occurred in Belgium in 1930. A thermal inversion occurred in an area characterized by concentrated industry with substantial amounts of sulfur dioxide emissions and discharges of particulate matter. Air circulation, which requires horizontal or vertical air currents, is one of the keys to the dispersal of air pollution. If there is no horizontal wind movement, then vertical air currents will usually disperse the pollutants due to the fact that atmospheric temperature is inversely related to height. The temperature falls by 5.4 degrees Fahrenheit every thousand feet above the Earth’s surface. So normally, the warm polluted air, being lighter, will rise and disperse into the cooler air.

However, if the temperature decrease is less than 5.4 degrees Fahrenheit per thousand feet, warm air, unable to rise because of the existence of even warmer air above it, hovers over the source of the pollution, trapping concentrated pollutants in the lower stratum. This phenomenon is called thermal inversion.

The thermal inversion in Belgium in 1930 resulted in sixty-three deaths and five thousand people becoming seriously ill. A similar episode occurred in Donora, Pennsylvania, a small industrial town thirty miles south of Pittsburgh, in 1948. Twenty people died and six thousand became ill. Thermal inversion combined with pollution and fog killed four thousand and caused numerous respiratory illnesses in London in 1952.

In the United States, the Donora incident led to a greater awareness of the problem of air pollution, and eventually to the Air Pollution Act of 1955. Although this act did little more than authorize and provide limited funding for research, it served as the basis for future amendments to the Act. The Clean Air Act of 1963 authorized the Public Health Service to take corrective action in addressing problems of interstate air pollution, and 1965 amendments gave the federal program the authority to curb auto emissions. The first standards for motor vehicle emissions were applied in 1968.

The Air Quality Act of 1967 strengthened the powers of state and local as well as federal authorities to set and enforce standards on a regional basis. This paved the way for the Clean Air Act of 1970, which was the first legislation to call for uniform air quality standards based on geographic regions.

The newly created Environmental Protection Agency (EPA) was given the authority to enforce two sets of standards: primary and secondary. Primary air quality standards concern the minimum air quality necessary to keep people from getting ill. These standards are based on proven harmful effects of individual pollutants. Secondary standards are intended to promote the general public welfare and prevent damage to plants, animals, and property in general. Within each geographic region, states determine how these standards are to be met.

MARKET APPROACHES TO AIR POLLUTION

Direct regulation or standards have been criticized on a number of grounds and have given rise to market approaches. Pollution taxes have been used, which it has been argued gives firms an incentive to reduce their emissions and is a lower cost method than command and control. The problem with such taxes or fees is identifying and calculating the social costs, and even if that is possible, there is no guarantee that they will reduce emissions to levels consistent with assimilative capacity.

These problems resulted in the market permits and emissions trading approach, which entails a market in pollution rights. The government makes some maximum allowable emissions standards, but then auctions off pollution permits to the highest bidders. Firms could purchase in the original market directly from the government or in secondary markets from other firms or individuals who purchased directly from the government, or in secondary markets themselves. Only after having acquired the right to pollute could a firm discharge polluting emissions. Here there is a tax incentive: The firm pays to reduce emissions and to seek ways of producing that pollution less, but the difference is that the total amount of pollution is fixed. In this sense, the market permit approach combines the strengths of both direct regulation and market approaches.

The market permits approach is not without its critics however. Many see the practice as government auctioning off clean air to the highest bidder. These issues are becoming particularly important as scientific evidence about problems such as global climate change becomes more reliable and available.

POLLUTION, NOISE

Noise pollution is undesired sound that is disruptive or dangerous and can cause harm to life, nature, and property. It is often said that noise differs from other forms of pollution in that, unlike atmospheric pollutants for example, once abated, noise leaves no residual accumulation in the environment or the human body. Noise does leave behind its effects, however, and these can deteriorate after continued exposure to harmful sounds. So it is not true, strictly speaking, that “noise … leaves no visible evidence” (Lai 1996, p. 389).

The hazardous effects of noise depend on its intensity (loudness in decibels), duration, and frequency (high or low). High and low pitch is more damaging than middle frequencies, and white noise covering the entire frequency spectrum is less harmful than noise of a specific pitch. Noise may be ambient (constantly present in the background) or peak (shorter, louder sounds).

Noise-induced hearing loss (NIHL) in humans is the major, though by no means only, problem stemming from noise pollution. In 1978 the U.S. Environmental Protection Agency (EPA) Office of Noise Abatement and Control estimated that around twenty million Americans were exposed daily to noise resulting in permanent hearing loss (EPA 1978). In 1990 about thirty million people in the United States were exposed daily to occupational noise levels above 85 decibels, compared with just over 9 million people in 1981. Exposure for more than 8 hours a day to sound in excess of 85 decibels is potentially hazardous. In Germany and other developed countries, as many as four to five million people, that is, 12 to 15 percent of all employed people, are exposed to noise levels of 85 decibels or more (World Health Organization 2001).

Loud, abrupt sounds can harm the eardrum, while sustained sounds at lower volume can damage the middle ear; both types of sounds can cause psychological damage. Noise disrupts sleep and communication, and numerous studies have documented the heart-related, respiratory, neurological, and other physiological effects of noise. Stress, high blood pressure, anger and frustration, lower resistance to disease and infection, circulatory problems, ulcers, asthma, colitis, headaches, gastrointestinal disorders, and many other physiological and psychological problems have been linked directly to noise. In addition, children have been shown to suffer from slower language development and disruption of learning as a result of noise. More than five million children in the United States, ages six to nineteen, suffer from noise-induced hearing impairment (Havas 2006). In the United Kingdom, Netherlands, and Spain, exposure to noise impaired children’s reading comprehension and caused a delay in reading skills development (Clark and Stansfeld 2005). In Austria, children in noisier neighborhoods were shown to suffer from increased stress and diminished motivation (Evans et al. 2001). A fetus exposed to noise may experience a change in heart rate, or it may suffer the impact of its mother’s noise-related stress.

In addition, noise can harm animals and the environment, as well as physical property. Livestock and pets are harmed by noise, as are animals in the wild. Noise can also disturb wildlife feeding and breeding. Noise-related property damage includes structural damage from vibrations induced by sound waves and economic harm in the form of lower property values. The true social costs of noise pollution also must include monetary losses from sickness, absenteeism, loss of productivity and earning capacity, and much more.

Noise pollution is not new, but it has become more problematic with the developments associated with industrialization and urbanization. Between 1987 and 1997, community noise levels in the United States were estimated to have increased by 11 percent and were predicted to continue increasing at that rate or more (Staples 1997). Commercial and industrial activities, construction, aircraft, vehicular traffic (highway and off-road), and the rapid increase in the use of machines and other technologies are all associated with noise pollution. Modern household appliances and lawn and gardening equipment are increasingly common sources of noise. Like many other forms of pollution, noise appears to disproportionately affect poor and disadvantaged minority communities, and so is also an environmental justice issue.

In the United States, public policy to address noise pollution began in the early 1970s. The Noise Control Act of 1972 charged the federal government with protecting public health and welfare from noise pollution by establishing standards for noise emissions and by authorizing federal agencies to establish rules. The EPA created the Office of Noise Abatement and Control (ONAC) as a result of the Noise Control Act. The Quiet Communities Act of 1978 authorized the EPA to provide grants to state...
and local governments for noise abatement. In the early 1980s the Occupational Safety and Health Administration (OSHA) set standards for industrial noise exposure and criteria for hearing protection. The OSHA guidelines resulted in a reduction of noise levels and hearing loss to workers, but some hearing loss can occur at OSHA-approved levels. In 1981 Congress agreed to the Ronald Reagan administration’s proposal to cease funding for ONAC, although Congress did not repeal the Noise Control Act when it eliminated ONAC’s funding.

Noise pollution can be controlled through reduction at the source, interruption of transmission paths, or protection of the receiver. Reengineering machines and simply turning down volume when possible are methods of reduction at the source. Barriers, enclosures, and other forms of soundproofing can interrupt transmission paths. The use of hearing protection is the main form of receiver protection. Experts recommend a multifaceted approach, including appropriate training on the use of equipment and on why ear protection matters, enforcement of hearing-protection regulations, and the use of new technologies that reduce noise at the source (Lusk et al. 2004). Like many other environmental problems, addressing noise pollution is complicated by issues of shared responsibility and jurisdiction, making some conventional economic approaches less effective and inviting new interdisciplinary solutions. New active noise control (ANC) technologies may assist in dealing with noise pollution in the years ahead through the use of digital processors that convert analog sounds into digital signals, allowing computer-generated “antinoise” to erase sound with sound (Alper 1991).

While market-based approaches to pollution control have become more popular in recent years, there have not yet been any emissions trading or pollution permits schemes applied to noise. It should be recalled, however, that up until the time of the first government regulation of pollution, a market-based approach was the “default” mode of pollution control.

POLLUTION, WATER

Water pollution exists when water is contaminated by impurities or its quality is otherwise adversely affected, for example, by solid matter or thermal discharges. Water pollution problems have a long history that can be traced to antiquity, and the attempts of communities to control such problems have an equally long track record. The nature of water pollution problems has changed over time, and their geographic scale has steadily increased, as has the scale of institutional solutions that have been adopted to control them. This entry explores the key changes in the nature and scale of water pollution and in the institutional solutions that have been adopted as a response to it.

Pollution of water by human wastes was a key public health problem when today's developed countries urbanized in the 1800s. Urban life expectancies decreased because contaminated water supplies caused epidemics of cholera, typhoid fever, and other water-borne diseases and increased people's susceptibility to all illnesses. These problems were initially local, when wells and ground water were used for water supplies, and communities responded to them with local public health and sanitation regulations. The construction of networked water supplies and sewer systems after the mid-1800s increased the scale of water pollution. Local regulations proved powerless when sources of pollution were increasingly outside the local jurisdiction. This situation gave rise to the first state and national water pollution policies, which successfully safeguarded public health but which largely failed to improve in-stream water quality.

The nature of water pollution changed in industrialized countries around the time of World War II (1939–1945) because the war effort and postwar recon-
struction resulted in the rapid growth of industrial production and increased discharge of industrial effluents. New innovations such as organic pesticides and synthetic detergents also proved potent water pollutants. The decades after the war witnessed several widely publicized environmental disasters, including mercury pollution in Minamata, Japan, that caused “Minamata disease” in the 1950s; the Torrey Canyon (1967) and Amoco Cadiz (1978) supertanker disasters in Europe; and the Santa Barbara, California, oil spill in 1969. Furthermore, there was controversy over asbestos-containing discharges from Reserve Mining into Lake Superior in Silver Bay, Minnesota, in the 1970s; the leak of toxic chemicals from the Sandoz factory in Basel, Switzerland, in 1986; and the cyanide spill from a gold mine in Baia Mare, Romania, which polluted the Tisza and Danube rivers in 2000. More recently, in November 2005, an explosion in a chemical plant in Jilin, China, polluted the Songhua River with benzene and nitrobenzene.

Water pollution continues to be a public health problem in the developing world. Worldwide, one child out of six under five years of age dies of a diarrheal disease such as cholera, typhoid fever, dysentery, and gastroenteritis, which are caused by the contamination of water by human wastes. Moreover, weak enforcement or the nonexistence of environmental and safety regulations in developing countries means that agriculture, horticulture, and mining are major sources of toxic water pollutants such as pesticides and mercury. Such pollutants have caused grave public health consequences across the developing world, but particularly in severely polluted areas such as the Aral Sea region in Central Asia. In some places, such as in Bangladesh, naturally occurring arsenic pollutes certain layers of ground water on which many communities depend for their water supply.

Most developed countries have adopted water pollution policies that have reduced conventional water pollutants from point sources. Conventional pollutants include biochemical oxygen demand (BOD), total suspended solids (TSS), fecal coliform, oil and grease, and pH (acidity and alkalinity). Point sources include municipal sewage treatment plants, industrial establishments, and other facilities, which only contributed about half of all conventional pollutants in the United States when the Clean Water Act of 1972, with its focus on point sources, was adopted. Water pollution originating from nonpoint sources, such as agriculture, streets and roads, and storm sewers, was not originally controlled with the same level of effectiveness. National policies have also been less successful in reducing the amount of nonconventional pollutants, such as those of toxic chemicals. More recently, market-based instruments such as fertilizer, manure, and pesticide taxes have been used in many countries for controlling water pollution from nonpoint sources. Other market-based instruments, particularly tradable effluent permits and sewerage charges, have increasingly been used also for controlling conventional water pollutants.

The incentives and capacity of states to control pollution from sources that lie outside their jurisdictions is limited, however. International environmental agreements have been negotiated to address this problem, including early agreements on the transportation of dangerous substances on the River Rhine in western Europe, which came into force between 1900 and 1902, and the Boundary Waters Treaty between the United States and Canada, which took effect in 1909. International agreements since 1970 have addressed, for example, the pollution of the marine environment by oil and dumping; the pollution of transboundary bodies of water such as the Baltic Sea, the North Sea, and the Mediterranean; the elimination of persistent organic compounds; and the international transport of hazardous materials and liability for damages caused by their transport. Some of these conventions, such as the 1992 Baltic Sea Convention, have been successful, while others have made little difference to the quality of the marine environment to date.

POLYARCHY

The term polyarchy was introduced into the English language in the seventeenth century as a term meaning “gov-
Polyarchy

government by many,” but later fell into disuse. Robert A. Dahl and Charles E. Lindblom revived the term in Politics, Economics, and Welfare (1953) to refer to a process by which non-leaders control leaders. Dahl subsequently revised and developed the concept, defining it in Polyarchy: Participation and Opposition (1971) as a political regime that is “highly inclusive and extensively open to public contestation” (p. 8), and in Democracy and Its Critics (1989) as a regime in which “citizenship is extended to a relatively high proportion of adults, and the rights of citizenship include the opportunity to oppose and vote out the highest officials in government” (p. 220).

The robustness and importance of the concept are derived from three features. First, polyarchy unambiguously refers to really existing modern representative democracies that have universal suffrage. Second, it does so by focusing on two dimensions essential to these regimes, participation and contestation. Third, polyarchy specifies a limited number of institutions that together are necessary and sufficient for its existence.

Polyarchy refers to the form of government found in contemporary democracies, but it is not the same as democracy. Dahl understands democracy to be a regime completely responsive to all its citizens. As such, democracy is an ideal, and polyarchy refers to regimes at considerable distance from the ideal. The institutions of polyarchy are held to be necessary for democracy on a large scale, but not sufficient. Though usually considered a “minimalist” concept of democracy, polyarchy nonetheless constitutes a significant human achievement. No country was a full polyarchy until the 1890s when women gained the right to vote in national elections in New Zealand, and until the 1990s only a minority of the world’s independent countries could qualify as polyarchies.

Polyarchy is a narrower concept than democracy in that it is comprised of just two of the many possible dimensions of democracy: political participation and contestation. Although the expansion of citizen participation in governing has been of great historical importance, in recent years universal suffrage has become widespread and most variation in polyarchy has occurred along the dimension of contestation. Polyarchy does not directly include many other dimensions often associated with democracy, such as the degree or extent of the rule of law, horizontal accountability, or actual government responsiveness to citizens, nor does it specify a level of political rights or civil liberties beyond that required for the effective presence of the institutions (listed below). Polities that qualify as polyarchies due to relatively high levels of competition and participation may vary significantly in other ways related to democracy.

Dahl has described the institutions of polyarchy, with some variation over the years. In On Democracy (1998) he lists them as:

1. Elected officials. Control over government decisions about policy is constitutionally vested in officials elected by citizens.…

2. Free, fair, and frequent elections. Elected officials are chosen in frequent and fairly conducted elections in which coercion is comparatively uncommon.

3. Freedom of expression. Citizens have a right to express themselves without danger of severe punishment on political matters broadly defined.…

4. Access to alternative information. Citizens have a right to seek out alternative and independent sources of information.… Moreover, alternative sources of information actually exist that are not under the control of the government or any other single political group.…

5. Associational autonomy.… [C]itizens also have a right to form relatively independent associations or organizations, including independent political parties and interest groups.

6. Inclusive citizenship. No adult permanently residing in the country and subject to its laws can be denied the rights that are available to others and are necessary to the five political institutions just listed. These include the rights to vote … [and] to run for elective office.… (pp. 85–86)

What is important for polyarchy is that each of these institutions must be effectively present, not merely a set of nominal rights. The degree to which these institutions are effective may be measured and a scale of polyarchy established, although polyarchy is often used dichotomously, with only those polities whose institutions are effective above a certain threshold qualifying as polyarchies.

Some authors have suggested that the list of institutions of polyarchy is incomplete and have proposed additions, while others have sought to provide more concise, accurate, or inclusive operational definitions of contemporary democracy than polyarchy. That most such attempts continue to use the concept of polyarchy as their starting point is testimony to its enduring usefulness.

**POLYTHEISM**

The term *polytheism*, referring to the worship of several gods, was coined in the sixteenth century. For medieval European Christians, the religious universe could be exhaustively categorized in terms of Judaism, Christianity, and paganism. This neat tripartite division was rendered obsolete by the Reformation. The first recorded use of the term *polytheism* was in a treatise against witches published in 1580 by the noted French thinker Jean Bodin (1530–1596). Significantly, Bodin also wrote an unpublished series of dialogues between “sages” who each practiced a different religion (including a Jew, a Roman Catholic, a Lutheran, a Calvinist, and a Muslim, among others) and who, unable in the end to resolve their differences, worshiped together in harmony. Bodin’s dialogue suggests a moral equivalence among all these religions that might be characterized as “monotheistic,” a term that would be invented slightly later.

This contrast between polytheism and monotheism appealed to secularizing Enlightenment thinkers precisely because it did not privilege Christianity. In particular, in *The Natural History of Religions* (1757), David Hume, deliberately turning his back on the biblical account, suggested that polytheism was the earliest form of human religion. It was not, he argued, born out of abstract speculation or contemplation, but rather in response to human hopes and especially fears—of illness, childbirth, war, and so on. Each such fear was governed by its own divinity, and because humans had an abundance of fears, they had a plethora of divinities. Only much later, according to Hume, did monotheism emerge as a (relatively) rational explanation of the world in terms of a single creator. In other words, polytheism was a religion of the passions, and monotheism a religion of reason. Hume was himself pessimistic about the capacity of reason to triumph over passion, and he envisaged the past and future histories of religion in terms of oscillation between the two poles of polytheism and monotheism.

The notion that “polytheistic” religions were emotional and irrational was used by Europeans to disparage non-European peoples and their religious practices. Charles de Brosses’s 1760 work *Du culte des dieux fétiches* (On the cult of the fetish gods) compared West African and ancient Egyptian religions in terms of their worship of gods who combined animal and human characteristics in a manner particularly repellent to Enlightenment criteria of rationality. Initially, late-eighteenth-century British observers of Brahmans’ Hinduism characterized it as essentially monotheistic, in light of ancient texts. However, in the nineteenth century, Hindu “polytheistic” worship was evinced as evidence of the degeneration of Indian society.

Beginning in the middle of the nineteenth century, emerging anthropological theories of social evolution easily incorporated the distinction between polytheism and monotheism into their vision of human progress. Most notably, Edward Tylor’s *Primitive Culture* (1871) traced the origins of religion to “animism,” the belief, derived from the experience of dreams, that there existed a “soul” independent of the human body. Primitives believed that animals, plants, and even inanimate objects also had souls, making nature worship the earliest and least rational form of religion. Polytheism, involving a hierarchy of greater and lesser gods and spirits, represented an initial advance, a step in the direction of monotheism and, ultimately, “scientific” atheism. Sigmund Freud gave this perspective a psychoanalytic twist in *Moses and Monotheism* (1939), associating the plural gods of polytheism with the different urges of the id, and the God of monotheistic religions with the superego.

Beginning in the early twentieth century anthropologists challenged the broad evolutionary schemes of their predecessors, preferring to concentrate on the intensive study of small-scale societies in the field rather than on “conjectural history.” Their studies were committed to demonstrating the rationality of non-European peoples and explaining their religious ideas in their own terms. They had little use for a term such as *polytheism* that, in their eyes, lumped a multitude of particular and radically different cultures and religious traditions into one broad rubric. Although the term was not the object of specific anthropological critique, anthropologists by and large avoided its use. The most conspicuous exception was E. E. Evans-Pritchard, whose influential study *Nuer Religion* (1956) described Nuer belief in and worship of a single “Spirit” (*kwoth*) alongside a host of greater or lesser “spirits” (*kuth*). The Nuer alternatively could be described as monotheists...
or polytheists, a contradiction Evans-Pritchard attempted to reconcile by suggesting that lesser spirits were in fact understood as refractions of the one Spirit from the point of view of specific groups or individuals.

However, too exclusive a focus on the religious particularities of small-scale societies obscured the ways in which multiple cults of divinities could proliferate regionally, nationally, and indeed transnationally. Hinduism is an obvious example. C. J. Fuller recently argued that “fluidity—which means that one deity can become many and many deities can become one—is a supremely important characteristic of Hindu polytheism” (Fuller 1992, p. 30). Not only does this allow the cult of greater divinities such as Vishnu, Shiva, and Devi to articulate with the local worship of tutelary gods and goddesses, but it also reconciles the seemingly antithetical eighteenth- and nineteenth-century characterizations of Hinduism as monotheistic and polytheistic. Similar examples can be drawn from West Africa, such as the cults of orishas among the Yoruba, and the cults of their neighbors who were transported across the Atlantic by the slave trade and formed Candomble in Brazil, Vodun in Haiti, and Santeria in Cuba. As with Hindu divinities, orishas have multiple names if not multiple personalities, and often are associated with specific localities. The myths that relate the principal orishas of the Yoruba pantheon to one another exist in multiple, and sometimes contradictory, versions. It is important to point out that individual worshippers form a personal bond with one specific orisha. Seen in this light, polytheism is not intrinsically a fixed and overarching system, but rather a highly flexible framework that can articulate local cults within a wider regional or supraregional framework. Attempts to systematize the theology and worship of such religions, most particularly Hinduism, are modern outcomes of colonial and post-colonial situations.

PONZI SCHEME

Ponzi scheme is the name given to any business or economic entity promising to pay a higher return to its investors than can be generated by this business’s net operating income. Operations of this type are sustainable only as long as funds from new investors or lenders are available to meet outstanding payout requirements.

This phrase originated in a get-rich-quick operation devised in the early twentieth century by Charles Ponzi (Zuckoff 2005). After immigrating to the United States from Italy in 1903 and serving time in prison, Ponzi launched his scheme in Boston in mid-1919. Ponzi’s operation was based on the arbitrage possibilities of the cross-border system of postal-reply coupons. In this system, people mailing documents internationally could send along coupons that enabled recipients to mail back the documents using stamps bought in the recipient’s country. The system used rates fixed in 1907 that had not been adjusted for subsequent currency realignments. Ponzi and his agents took advantage of this system by converting funds into devalued currencies, using those monies to purchase postal-reply coupons, trading them (at 1907 par values) for postal coupons in countries with stronger currencies, then converting these stronger countries’ coupons back into currency.

Ponzi obtained funds for his plan by offering a 100-percent return in ninety days. By July 1920 he had attracted millions of dollars to his Security Exchange Company. His scheme triggered an investment mania, and he began living luxuriously. Most of the returns paid to investors in Ponzi’s schemes came from new investors’ funds, not from postal-coupon investment earnings. Ponzi’s scheme was exposed by the U.S. Postal Service, and federal agents raided the Securities Exchange Company in August 1920, rendering worthless the stakes of his 17,000 investors. After serving more time in prison, Ponzi was deported to Italy; he died at a charity hospital in Rio de Janeiro in 1949.

Ponzi schemes have arisen frequently, both in the past (Kindleberger 1978) and in the present. Many Ponzi schemes now operate on the Internet. Such schemes can be sustained as long as existing investors do not liquidate their positions, and as long as new investors opt in and regulators do not intervene. When a bailout is expected, it can be rational to participate in a Ponzi scheme (Bhattacharya...
These schemes resemble asset bubbles in that investors in both cases suspend belief and are often driven by greed; but asset bubbles arise in open markets with changing sets of investors, whereas Ponzi schemes arise via closed contracts made to well-defined sets of investors. Pyramid schemes are one variant of the Ponzi scheme in which the earlier in the scheme a participant signs on, the greater that person's share of excess returns.

Economists increasingly describe any situation as "Ponzi" when it involves payout obligations that can be met only through borrowing against future income. For example, in his theory of financial fragility, Hyman Minsky (1975) used the term Ponzi finance to denote the borrowing requirement of firms whose cash flow from current operations is insufficient to meet current liability obligations. Thomas Sowell (2003), among others, has argued that social security systems have Ponzi characteristics, in that old-age benefits liabilities are transferred across generations instead of being self-financed. Other economists, such as Stephen O'Connell and Stephen Zeldes (1988), have modeled the behavior of governments with growing fiscal deficits as Ponzi games.

POOLED TIME SERIES AND CROSS-SECTIONAL DATA

Economic datasets come in a variety of forms. The cross-sectional, time series, and panel data are the most commonly used kinds of datasets. A cross-sectional dataset consists of a sample of individuals, households, firms, cities, states, countries, or any other micro- or macroeconomic unit taken at a given point in time. Sometimes the data on all units do not correspond to precisely the same time period. In a pure cross-sectional analysis, such minor time differences in data collection are ignored. Figure 1 illustrates the relationship between cross-sectional data on the price of houses sold within a two-week period and the houses’ size. The basic model, $y_i = c + x_i \beta + \varepsilon_i (i = 1, 2, \ldots, N)$, where $y_i$ is the dependent variable and $x_i$ is a $1 \times K$ vector of explanatory variables, often has stochastic errors $\varepsilon_i$, such that $E(\varepsilon_i/x_i) = 0$ but $V(\varepsilon_i/x_i) = \sigma_i^2$. Ordinary least squares (OLS) estimates that ignore heterogeneity across cross sections are unbiased but inefficient. Efficiency can be attained from generalized least squares (GLS) estimation. In economics, the analysis of cross-sectional data is closely associated with applied microeconomics fields such as labor economics, public finance, industrial organization, urban economics, demography, and health economics. Data on individuals, households, firms, and cities at a given point in time are important for testing microeconomic hypotheses and evaluating economic policies.

A time series dataset contains information on a variable or a set of variables over time. Examples of time series data include stock prices, money supply, the consumer price index, gross domestic product (GDP), annual homicide rates, and automobile sales figures. Figure 2 illustrates the time series for NASDAQ on July 7, 2006. Since past events influence the future and lags in behavior are prevalent in the social sciences, time is an important dimension in time series datasets. Unlike the arrangement of cross-sectional data, chronology is crucial in time series datasets. Time series observations are hard to analyze mainly because of the interdependency of observations over time. The basic model, $y_t = c + x_t \beta + \varepsilon_t (t = 1, 2, \ldots, T)$, where $y_t$ is the dependent variable and $x_t$ is a $1 \times K$ vector of explanatory variables, has stochastic errors $\varepsilon_t$ such that $E(\varepsilon_t/x_t) = 0$ but $\varepsilon_t = \rho \varepsilon_{t-1} + u_t$ ($u_t$ satisfies all classical assumptions).

Most economic data are strongly related to their recent histories. For example, information on GDP from the last quarter allows the researcher to make accurate predictions about the likely range of GDP during the current quarter, because GDP tends to remain fairly stable from one quarter to the next. OLS regression estimates that ignore the time-dependence features of time series data produce inaccurate results. Model transformation is required to produce GLS estimates that are efficient. Several modifications and embellishments to standard econometric techniques have been developed to account for and exploit the dependent nature of economic time series and to address other issues, such as the fact that some economic variables tend to display clear trends over time.
Another feature of time series data that can require special attention is the frequency at which the data are collected. In economics, the most common frequencies are daily, weekly, monthly, quarterly, and annually. Stock prices are recorded daily (excluding Saturday and Sunday). The money supply in the U.S. economy is reported weekly. Many macroeconomic series, such as inflation and unemployment rates, are tabulated monthly. The gross domestic product is a quarterly series. Other time series, such as the infant mortality rates in the United States, are available only on an annual basis. Many weekly, monthly, and quarterly economic data display strong seasonal patterns. For example, monthly data on crop yield differ across months simply due to changes in weather conditions. Hence, before analyzing time series data, it is important to deseasonalize the data or remove the seasonal trends.

A panel or longitudinal dataset varies across both time and cross-sectional units, as seen in Figure 3. This is a partial table of the entire dataset that consists of the value of sales \((sal)\), payroll \((pay)\), capital expenditure \((cap)\), and cost of pollution abatement \((abat)\) for a set of industries followed over a three-year period. The ordering of the data by microunits first and then by time is typical of all longitudinal datasets. The number of time periods are kept constant across the cross-sectional units in balanced panels. Treatment for unbalanced panels requires further analysis.

The basic model for the \(i\)th cross section is \(y_{it} = c_i + x_{it}\beta + u_{it} (t = 1, 2, \ldots, T)\), where \(x_{it}\) is a \(1(K)\) matrix of explanatory variables that vary across \(i\) or \(t\) or both, \(c_i\) represents cross-sectional heterogeneity, and \(u_{it}\) is a stochastic error. The conditional mean of the disturbances is assumed to be zero. In traditional approaches, the model is random effects (RE) when \(c_i\) is a random variable, and fixed effects (FE) when \(c_i\) is a fixed parameter to be estimated (Balestra and Nerlove 1966). Yair Mundlak (1978) made a valid argument that unobserved effects \(c_i\) should be treated as random draws from the population along with \(y_{it}\) and \(x_{it}\). In modern econometric language, in an
RE model, \( c \) is assumed to be uncorrelated with \( x_{it} \), while in a FE model, arbitrary correlation between \( c \) and \( x_{it} \) is allowed.

Two famous studies that analyze panel datasets are the National Longitudinal Survey of Labor Market Experience (NLS) and the Michigan Panel Study of Income Dynamics (PSID). In these datasets, very large cross sections, consisting of thousands of microunits, are followed through time, but the number of time periods is often small. The PSID is a study of roughly six thousand families and fifteen thousand individuals who have been interviewed periodically from 1968 to the present. Another group of intensely studied panel datasets are those from the income tax experiments of 1970, in which thousands of families were followed for eight to thirteen quarters. For most panels, cross-sectional dependence is strong and time dependence is insignificant. Panel datasets are wide but short, and heterogeneity across units is often the central focus of the analysis. In two-way error components models, the cross-sectional heterogeneity varies across time and cross sections, that is, \( y_{it} = c_{j} + x_{it}\beta + u_{it} \) or \( y_{it} = c_{i} + \delta_{t} + x_{it}\beta + u_{it} \). The fundamental advantage of a panel dataset over a cross section is that it allows the researcher greater flexibility in modeling differences in behavior across individuals.

POPPER, KARL

1902–1994

Sir Karl Raimund Popper was a leading twentieth-century philosopher. His first major work, *Logik der Forschung* (The Logic of Scientific Discovery, 1935), was a methodology of the physical sciences that dispensed with induction. His second major work, in two volumes, *The Open Society and Its Enemies* (1945), was a democratic manifesto that burst out of broad yet incisive discussions of the philosophy of history, society, and politics. Slightly less influential was his slim, sober *Poverty of Historicism* (1957).

David Hume’s (1711–1776) critique of induction—that universal statements of science never follow deductively from particular statements describing experience—inadvertently undermined the rationality of science. His own response to his critique was to base inductive inferences on habit rather than on rationality. Immanuel
Kant's (1724–1804) response was to base inductive inferences on the principle of induction (or of simplicity, as he called it), whose status is that of extralogical truth known with no recourse to experience: synthetic a priori knowledge. Most philosophers find Hume's response a retreat to irrationalism and Kant's response a retreat to dogmatism. They sought a different way around Hume's critique. Thus, the problem of induction, the search for a satisfactory response to Hume's critique, became a central concern of rationalist philosophy. Popper rewored the problem: how is theoretical learning from experience possible? To this, he had a new solution: learning from experience is deductive; it advances by the refutation of bold conjectures; and the bolder the better. The view of learning from experience by refutations is impervious to Hume's critique: a statement of experience conflicts with a theory. Thus, contrary to Kant, Popper viewed science as no knowledge, much less as a priori knowledge. Science then is the search for explanatory conjectures and for ways to test them. He thus shifted traditional epistemology from the positive to the negative, to via negativa: groping in the dark and learning from error. He likewise turned traditional positive epistemology into Socratic negative epistemology: we know that we do not know, we know the limitations of some theories. Our pursuit of knowledge engenders our best and most interesting errors.

Popper's view aimed to account for the progress of science, not for its alleged reliability. On this he made three very important comments. First, absolute reliability is impossible and conditional reliability is question-begging. Second, most applied theories and the most frequently applied ones—Galileo's (1564–1642) and Isaac Newton's (1642–1727)—are refuted. Third, current efforts to answer Hume must be hopeless and useless. In particular, reliability is not probability; to the extent that it is possible it is the elimination of some dangerous applications of science achieved by severe tests. Following probability is caution, whereas scientific thinking is bold and so are attempts to apply it. Yet because theories are hypotheses that invite critical discussion, a testable theory of induction may be welcome, but most proposed solutions of the problem of induction are untenable and so they are pseudoscientific.

Popper's contribution to social and political philosophy accords with his negative philosophy of science. It is more significant, both politically and intellectually. He argued that any regime that safeguards the means for peaceful corrections of government errors deserves respect as a democracy. Politics invites criticism aimed at improvements, he observed, and seeking improvements is superior to—more fruitful than—the traditional theory of the sovereign that is a futile search for the best regime. This is the central message of Popper's philosophy, both theoretical and practical, regarding science, government, and anything else worthwhile: improving is preferable to legitimating. He took particular aim at intellectuals, arguing that they had moral responsibilities commensurate with their privileges and that they had a long history of falling short. As examples, he expounded the ideas of two of his greatest intellectual heroes, Plato (427–347 BCE) and Karl Marx (1818–1883). He claimed that their devotees glossed over the defects of their philosophies, especially their illiberalism. His doctrine that great men make great mistakes from which we should learn was more challenging than his negative epistemology.

Popper deemed unscientific the doctrines of historical inevitability or historical destiny (historicism in his jargon) of Plato and of Marx. He said that no doctrine of this kind can be worded in a manner clear enough to be put to the test of experience, because if such a theory were to cohere with known facts, it must be vague. (Irrefutable versions of historicism are easy to invent: the simplest is the purely existential "historical destiny exists.") Ingeniously, Popper found a way to refute all reasonable versions of historicism, despite its inherent vagueness. The argument deploys two intuitive premises: future science is in principle unpredictable, and its impact on society is tremendous. Hence, no large-scale theory of the future development of society can possibly yield significant or interesting predictions.

Popper's mode of thinking leads to his greatest and most significant idea. It is his replacement of the theory of rationality that characterizes Western philosophy. Most people take for granted the idea that the best culture is their own. The first to reject this idea as too complacent were the leading ancient Greek philosophers. They deemed problematic all cultures, and what cultures espouse as true they declared to be nonbinding, conventional truths. They deemed binding only universal, absolute truths—truths by nature. Proof is required to show that an assertion is true by nature.

Popper challenged this doctrine: applying the Socratic maxims to science, he declared its rationality to rest neither on proof nor on surrogate proof but on willingness to engage in critical debate. This willingness creates a balance between tradition and science, between conservative and radical politics, between the given and the hoped for: it is a plea for reformist democracy, a view of scientific progress as an approximation to the truth and to freedom and justice, a view that applies to all walks of life, a remarkable and exciting move towards a synthesis and a challenge to push it forward. As the root of rationality is willingness to debate, reform is secondary to the replacement of both traditionalism and radicalism with the advocacy of individual autonomy.

POPULAR CULTURE

Popular culture is the domain of cultural products created in mass quantities for a mass audience. While folk culture is the realm of face-to-face culture in small groups and high culture is the realm of cultural products produced by a few for the few, popular culture is more public than folk cultures and more easily accessible than high culture. Popular culture often appropriates ideas, forms, and formulae from both folk culture and high culture. In modern industrialized societies, popular culture appeals to the broad middle class and generally reinforces that class’s views of the world.

THE ORIGINS OF POPULAR CULTURE

Although some historians argue that popular culture is very old, most scholars believe that popular culture in its present forms emerged in the nineteenth century when communication technologies (e.g., printing processes and photographic reproduction) and large-scale media organizations (newspapers, magazines, book publishers) were able to create and market messages for a large audience of consumers. Modern popular culture required the development of commodity capitalism, the stage of capitalist development when the problem of production had been solved (through technology and bureaucratic organization), leaving the problem of consumption of the goods and services produced by the society. Advertising, a form of popular culture, plays a crucial role in the creation of desire to consume the commodity goods and services produced in a capitalist society.

The role of print and electronic media (print, then film, radio, television, and Internet-based communication) in the dissemination of popular culture products leads some critics to call this realm “mass-mediated culture,” and the role of markets and consumers since the latter part of the twentieth century has led some to call this realm “commodity culture.” Whatever the term the key elements in identifying and analyzing popular culture are its mass production and mass consumption, often “mediated” through channels of communication that stand between the producers and consumers of the cultural products. Scholars who study popular culture believe that patterns of production, dissemination, and consumption in this realm of culture reveal much about the values and beliefs of the audience. The assumption is that if people will spend money to consume a product or an experience, then they expect that experience to satisfy some need or desire. The nature of commodity capitalism, of course, is that the satisfaction experienced by consuming popular culture products and experiences is fleeting, always bringing the audience (the customer) back for more.

Some genres of popular culture include familiar sorts of “texts,” including popular fiction, magazines, advertising, film, radio programs, comic books, cartoons, television programs, recorded music, and even fast food. Other genres appear as more complex social events or experiences, such as popular music concerts, sporting events, entertainment events (e.g., professional wrestling), visits to amusement parks, leisure pastimes, or tourist experiences. In all of these cases and more, the critical element is that a mass audience pays money to consume the commodity or experience.

POP CULTURE AND SOCIAL CLASS ISSUES

Social class issues pervade discussions of popular culture. Access to the economic resources one needs to consume the products of popular culture is one of these issues, but equally important has been the issue of “taste cultures,” the idea that different social classes acquire different tastes.
Popular Culture

in arts and entertainment, for example. Popular culture has been dismissed by some critics as "middlebrow," a judgment that its quality is not on par with high culture, but defenders of popular culture champion it as the distinctive product of democratic societies.

Social scientists became interested in popular culture in the 1920s as Marxist scholars and others began to realize that commodity capitalism was creating a whole new realm for struggles between ideologies and centers of power. A group of intellectuals affiliated in these years with the Institute for Social Research at the University of Frankfurt am Main in Germany (known as “The Frankfurt School” of social thought and criticism) began rereading German political philosopher Karl Marx (1818–1883) and adding Sigmund Freud’s (1895–1939) psychology of the unconscious, thereby developing a “critical theory” of society that saw the products of popular culture as a more effective means by which one class of people establishes hegemony in society, persuading with words and images rather than with class violence. Especially relevant to understanding popular culture is Walter Benjamin’s 1936 essay, “The Work of Art in the Age of Mechanical Reproduction,” which belongs to this period and school of social criticism and lays the groundwork for important inquiry into issues of authenticity, the political uses of popular art, and the possibilities of cultural change in a world of mass production and consumption.

Social scientists in the United States were a bit slower than their European colleagues to realize the importance of popular culture. In their 1929 and 1937 studies American sociologists Robert S. (1892–1970) and Helen Merrell Lynd (1896–1982) noted the importance of popular entertainments in the lives of their Middletown (Muncie, Indiana) families, but it was in the postwar years that sociologists like Paul Lazarsfeld, Kurt Lewin, Harold Laswell, Carl Iver Howland (1912–1961), David Riesman, and C. Wright Mills (1916–1962) took mass-mediated culture seriously as the realm where middle-class ideologies of gender, race, social class, and American “exceptionalism” were exerting their power. After struggling for legitimacy in the academic world through the 1950s, the academic study of popular culture finally took hold in the 1960s. In the next decade a new cluster of ideas came from those working at the University of Birmingham Centre for Cultural Studies and elsewhere in Great Britain, again informed largely by Marxist thought. British cultural studies recognized the importance of popular culture and saw in youth cultures and in other subcultures the potential (often squandered) for resistance. As Americans and then others picked up and elaborated on the ideas offered by the Birmingham School, the study of popular (mass-mediated, commercial) culture moved to the center of these social scientists’ interest in power and ideology.

PRODUCTION

Some social scientists ask and answer questions about the societal circumstances and organizations that produce popular culture. Historian and cultural studies scholar Raymond Williams, for example, led the way in creating a "sociology of culture" in the 1970s and early 1980s. His 1974 book Television: Technology and Cultural Form is a classic piece of cultural studies criticism, and a generation of sociologists, historians, and communications scholars has continued the examination of the ways mass media corporations organize production, create popular culture products, disseminate the products, and exert control over other organizations and realms of society. Of special interest to some scholars is the concentration of media power by certain corporations, including powerful transnational corporations, and how this affects society.

CONSUMPTION

Humanists brought to the initial media criticism of the 1950s their familiar methods from literary and art criticism, but social scientists had their own methods for understanding the meaning of texts. Content analysis of films, television shows, advertising, and other popular culture genres was a favored method of popular culture analysis for a time, and some theories of textual criticism (e.g., semiotics) provided an interdisciplinary bridge between humanistic and social scientific approaches.

The problem with most media textual criticism, whether it used humanistic or social scientific methods or a combination of these, is that the criticism appears to assume that the meanings of a popular culture text or experience are determined by the author(s) of the text. British cultural studies, especially the work by cultural theorist Stuart Hall and his colleagues, challenged that author-based model of the meaning of texts and in its place developed the position that the meanings of a popular culture text or event is a product of the active interaction between the text itself and the audience consuming the text. The creators of the popular culture may have “encoded” a series of meanings in a text or event, noted Hall, but the audience “decodes” the communication and need not accept the hegemonic reading of the text desired by the creator. Some readers or viewers might have the resources to formulate an oppositional understanding of the text, while others may adopt a more “negotiated” stance, accepting some of the creators’ meanings and rejecting others.

This new view of the agency of the audience led critics to see that they would have to do fieldwork with audiences or otherwise engage in exchanges with audiences so that the critic could see how people were making their own meanings out of popular culture texts and experiences. Some social scientists use broad survey instruments for their audience response analysis. Others use interview
methods with focus groups of audience members. Some put themselves in the natural settings with audiences (e.g., at Disney World) and observe how the audience interacts with and talks about the experiences.

GLOBALIZATION AND NEO-IMPERIALISM
The products of popular culture easily cross geopolitical boundaries. National film industries quickly became international, for example, but this is also true for other popular art forms, including music, literature, television, and comics. By the 1930s American films were dominating the world markets, but it was World War II (1939–1945) and the occupation of Europe and Japan by U.S. soldiers that accelerated the foreign appetite for American popular culture, in particular music, film, clothing (especially blue jeans), and comic books. By the 1950s the increasing globalization of the corporations producing popular culture was leading to what critics came to call “the Coca-Cola-ization” of the world, as it was hard to find any place in the world without that soft drink and the advertising for its consumption.

Some scholars and critics point to this international dissemination of American popular culture as a form of “neocolonialism” or “neoimperialism” by which the United States exerts ideological influence on other nations through its popular culture. Governments and nationalist social movements sometimes have resisted this American world hegemony through popular culture. Cultural studies expert Paul Gilroy and other critics see a different sort of neocolonialism in the field of cultural studies itself. Gilroy’s work on the transnational movement of African people and their cultural products makes an explicit critique of the racial assumptions and of the Anglocentric and Eurocentric focus of some cultural studies scholarship.

Although American popular culture still dominates the world markets, the flow of popular culture across borders became more complicated in the turn of the twenty-first century. Japanese animated television series and films (anime) and Japanese graphic novels (manga) became very popular among American and other youth, and Korean popular culture (musical groups and television serial dramas, for example) became very popular in Japan. Scholars have mapped “world music” cultures and the movement of the music across cultural boundaries. These trends have raised speculation that there is emerging a transnational youth culture linked by communication technologies and creating a shared culture through music, dress, video games, and television.

NEW TECHNOLOGIES
Popular culture has depended on advances in technology since the nineteenth century. Technologies of mass production and mass distribution made possible newspapers, magazines, and popular fiction (from dime novels to comic books to paperback novels). Popular music and the technologies of sound production have always been intertwined. Songwriters wrote to the time limits possible for recordings, and scholars have noted the effects of electronic amplification of music on the art of the music itself. The history of film is as much a history of technological change as of artistic change, and digital moving images may actually make film an archaic technological medium. Radio continues to evolve with the technologies, as the new satellite radio manufacturers and stations overcome the limitations of atmospheric broadcast and as increasing numbers of people listen to radio through their computers. Musicians and the companies that produce and market popular music have had to adjust to digital technological advances that make artistic and intellectual property rights difficult to enforce, as people use their computers to share music, films, and television shows. Young people seem to be “platform agnostic,” as some critics call the tendency to move easily between different technologies for consuming music, film, and television. These technologies add to the globalization of popular cultural products.

The new technologies of communication are having effects on social interactions that scholars are still trying to understand. Several studies make clear the role of social class in the uses of these technologies, and several worry that the gap between rich and poor people in the world will be widened by this technology gap.

Scholars are also interested in the cognitive effects of these new technologies for disseminating and consuming popular culture. American cultural historian Walter J. Ong studied the cognitive effects of our move from primarily oral cultures to written cultures, which led him to speculate that there is a “secondary orality” emerging in electronic communication. Furthermore some scholars argue that new media entertainments, including video games and computer games, actually require increasingly complex cognitive skills, from spatial intelligence to the ability to keep track of multiple storylines and characters. The advancements in cognitive and mind sciences make it likely that those working in these natural science disciplines will collaborate even more with the social scientists studying popular culture toward understanding the social and cognitive effects of mass mediated experiences.

POPULAR MUSIC
While music that “the people” listen to has always been present, popular music as it is known today is a recent phenomenon dating to the late nineteenth and early twentieth centuries. Several factors are responsible for bringing about the rise of popular music. One is technological: New technologies for the reproduction of music, such as the player piano and phonograph in the late nineteenth century and radio and sound film in the 1920s, greatly facilitated access to music, and helped prompt a proliferation of different musical styles. Another factor was the rise of consumer culture, as people increasingly came to understand themselves less through their occupations, as producers, and more through the ways that they spent their leisure time, as consumers. The growth of the modern advertising industry helped push this process along; manufacturers of player pianos and phonographs spent heavily promoting these technologies early in the twentieth century.

Yet another factor was the increased industrialization of the production of music. Modern management techniques derived from Frederick Taylor (1856–1915) and Henry Ford (1863–1947) found their way into the music business, which became increasingly rationalized, more like a business that manufactured everyday commodities.

At the same time that these developments were occurring, new musical styles were entering people’s consciousness. The craze for ragtime piano music in the late nineteenth and early twentieth centuries helped fuel player piano sales. Jazz, blues, and other African American musical styles helped the American recording industry market African American performers to a broader white audience under the rubric of race music.

Perhaps most significant, however, was the rise of radio. Radio in the moment of its popularization, the mid-1920s, boasted greater fidelity than phonograph records and did not have the three-minute time limitation of 78 rpm recordings. And early radio was live. Listeners around the country were in thrall to dance music, which was essentially highly arranged, sanitized jazz performed by white musicians such as Paul Whiteman (1890–1967). The sensitivity of electrical microphones for radio resulted in a new style of singing called crooning in which performers sang in a much more intimate way than when they sang without amplification in auditoriums. This style produced the first mass-media popular music superstars in the United States, such as Rudy Vallée (1901–1986) and Bing Crosby (1903–1977), who helped define a mode of popular musical superstardom that paved the way for later figures such as Frank Sinatra (1915–1998) and Elvis Presley (1935–1977).

After World War II (1939–1945), the invention of magnetic tape made the production of recordings much less expensive, and many small record labels sprang up to capture the sounds of African Americans who had moved from the South seeking employment. Their urban blues gave rise to rock and roll, which found a consumer base in the newly developed marketing category of teenagers in the postwar era of intensified consumption practices.
Rock and roll helped give some types of popular music, as well as musicians, greater influence and prestige than either had known before.

Today, popular music is a multinational, multibillion-dollar business dominated by American and European stars, as well as American, European, and Japanese record labels whose products are sold and traded digitally around the world. Hundreds of local styles globally are influenced by American and European sounds, some of which are picked up by labels with international connections and are marketed as world music.

**POPULATION CONTROL**

Concern over uncontrolled population growth already existed in ancient times when scholarly discussion of population issues and evidence of efforts to control family size were recorded in Greece, China, and some other areas (Potts 2003; Zhao 2006). The advocacy for population control has grown notably since the eighteenth century, when population growth began accelerating in many parts of the world.

Population control has been promoted mainly because of the following considerations: To prevent a fall in living standards and the consequences of such a fall, population growth should not outstrip the growth of subsistence. The growth of the population needs to be contained within the biophysical carrying capacity of the earth, otherwise it will lead to overexploitation of natural resources, greatly damaging the ecosystem. In addition to such economic and environmental concerns, promotion of population control also reflects people’s varying views of social reform and is regarded as an important step toward enhancing the health of women and their families, protecting people’s reproductive choices, and improving sexual expression for both sexes through freedom from fear of pregnancy. In the early stages of its development, population control was also closely connected to the spread of social Darwinist ideas and the eugenics movement.

Population control can be achieved through various means, including those labeled by Thomas Malthus (1766–1834) as positive checks, such as war, famine, disease, and infanticide, that increase death rates (Malthus [1803] 1989). The most significant development in recent human history, however, has been the family-planning or birth-control movement, which is the focus of the remainder of this entry.

The family-planning movement began in Europe. Increasing use of contraception (mainly coitus interruptus and the sponge) was first observed in France in the eighteenth century. Ideas and knowledge of birth control spread in Europe (in Britain in particular) and the United States in the nineteenth century when a number of publications about family planning were widely circulated. The first family-planning clinic was established in the Netherlands in the 1880s. During the next few decades, the number of family-planning clinics and organizations promoting birth control grew markedly in Europe and North America. Because of widespread family planning, fertility had already fallen to a very low level in some populations by the early twentieth century.

Significant political and socioeconomic changes took place in many countries after World War II (1939–1945). The baby boom and rapid mortality decline together led to unprecedented population growth, which further stimulated the development of the family-planning movement. Between the 1950s and 1970s, an increasing number of countries began offering family-planning services. The financial and technical assistance provided by developed countries and international organizations greatly helped family planning in less-developed countries. Modern and easy-to-use contraceptives, such as the intrauterine contraceptive device and the birth control pill, became widely available and provided women with greater choice. By the mid-1980s, family-planning programs flourished worldwide. Forty percent of national governments regarded fertility in their countries as too high, 32 percent had official policies to reduce fertility, and 86 percent directly or indirectly supported access to contraception (Tsui 2001). In the first decade of the twenty-first century, world contraceptive prevalence rates exceeded 60 percent among women of reproductive age (United Nations 2006).

It is nonetheless noteworthy that different views toward family planning and population control could be found throughout the twentieth century. For example, concern over low fertility and depopulation already existed in France and some other Western countries in the 1920s, and this concern had grown by the end of the century. In less-developed countries—especially those with relatively low population densities—environmental degradation, poverty, and many other social problems are regarded by some as the result of inequality in the distribution of power and wealth, rather than the outcome of
uncontrolled population growth (Hodgson 2003). It is also argued that increasing population density could stimulate economic growth, rather than constrain it (Boserup 1965; Simon 1996).

Although family-planning programs exist in both developed and less-developed countries, there are noticeable differences between them. In most developed countries, family planning started in the nineteenth century or early twentieth century. It was largely a private and philanthropic enterprise and primarily for the purpose of granting individuals, especially women, control over their own reproduction. Programs were organized and executed mostly by voluntary family-planning associations, and governments played no part in this great social-demographic change. The early reduction of fertility was achieved largely through the use of traditional contraceptive methods. In less-developed countries, by contrast, family planning began mainly in the second half of the twentieth century. Rapid population growth in these countries was often seen as a constraint upon socioeconomic development. Family planning was adopted as an official policy to release such pressure, and was directly organized and financed by the government. In some countries, incentive and disincentive (sometimes coercive) measures were employed to induce people to regulate their reproduction. The role of modern contraceptive methods in controlling fertility was crucial in these programs.

China's family-planning program is one such example. Although family planning was promoted in some Chinese cities in the first half of the twentieth century and then again in the 1950s, China's nationwide family-planning program did not start until the early 1970s when its population reached more than 800 million. Facing this pressure, the “later-longer-fewer” policies (which encouraged people to postpone marriage and childbirth to older ages, to prolong birth intervals, and to reduce family size to one or two children) were formed and implemented through a nationwide family-planning network. Even though a great reduction in fertility was achieved between 1970 and 1978, the Chinese government further tightened its birth-control policies in 1979. In cities and advanced rural areas, couples were asked to have only one child; in other rural areas, a family could have no more than two children, although there were exceptions. These radical policies remain in effect, with minor modifications, through the use of both incentive and punitive measures, in addition to the vigorous promotion of family planning. By 2007 China's family-planning program had met its demographic goals, and the country's total fertility rate had been below replacement level for more than a decade. Despite this achievement, China's family-planning program has been accompanied by some negative developments, such as rising sex ratios at birth and an increasing number of induced abortions (similar trends have also been observed in other countries). These developments, which are related to China's long cultural tradition of son preference and the implementation of strict birth-control policies, have made the program very controversial.

At the beginning of the twenty-first century, largely due to the family-planning movement, high fertility or uncontrolled population growth was no longer an issue in many parts of the world. Many developed and some less-developed countries had experienced below-replacement fertility rates for more than a generation, and a few had even experienced a population decline. Indeed, some countries are now taking action to reverse these trends. However, fertility is still high in some countries (mainly in sub-Saharan Africa and the Middle East), where further improving family-planning services remains a major concern.

**POPULATION GROWTH**

Population growth (positive or negative) is caused exclusively by the operation of fertility, mortality, and migration. Regarding the population growth of countries and
other national populations, the effect of migration is normally not as influential as the effects of fertility and mortality, usually considered to be the major factors directly causing national population growth (Hinde 1998). However, regarding the population growth of the subareas (states, provinces, counties) of national populations, migration is the single most important of the three demographic processes. Differences in birthrates and death rates in subareas of the same country are typically small compared to differences between the subareas in migration. Migration is thus the major method for redistributing the population within a country.

Fertility is a source of population growth because the number of births indicates whether a population is in a growing pattern (Hinde 1998). If a fertility rate, say the total fertility rate (TFR), is above 2.0, this indicates that on average a woman has more than two children in her lifetime. If the TFR is above 2.1, it means that the woman on average has above replacement fertility, allowing the population to grow via fertility. Mortality is also important given that the death rate determines the number of people who will no longer be able to contribute to the growth of the population. Controlling fertility, countries with high age-specific death rates in infancy and childhood are more likely to have fewer people to give birth to children and thus slower and sometimes negative rates of population growth. Constant fertility and mortality rates typically produce constant population growth rates (Hinde 1998).

The rate of population growth is not only a demographic phenomenon, it also has a broad impact on the society and people's lives. For instance, researchers have found relationships between population growth and economic growth (Barlow 1994; Blanchet 1992; Coale 1986). Robin Barlow (1994) has argued that in a relatively short period of time, an increase in fertility tends to have a negative effect on the economy, while in the long run the opposite relationship is true. Population growth can also lead to a rising demand for food. Problems of instability in food production are particularly difficult for some developing countries with high population growth rates and low technological changes in agriculture (Mellor 1982). In addition rapid population growth tends to impact the interactions between human beings and their environment. An increasing number of people in the population leads to pressures on land resources, which limits the amount of arable agricultural land and tends to worsen the situation of food supply and human reproduction (Shaw 1976). Furthermore a high rate of population growth is likely to increase population density in certain geographic areas, particularly urban settings. As a result overcrowding, unemployment, and poverty are likely to lead to social problems in some localities (Sibly and Hone 2002).

From a microperspective, the population growth rate also has significant influences on an individual's life. Researchers have found that population pressures tend to affect individuals' social reactions. They either force individuals to withdraw from social life as methods of escape or protection due to social overload (Baum and Koman 1976; Evans et al. 2000), or they provoke competition for resources, which tends to amplify people's aggressive behaviors (Calhoun 1962; Lorenz 1967). The latter reaction is often used to explain deviant social behavior in overly crowded areas (Regoecri 2002). Residential overcrowding has also been found to have an effect on individual well-being and family relations. Children in crowded households have sometimes been observed to have difficulties in behavioral adjustment at school, to perform poorly in academic settings, and to have vulnerable relationships with their parents (Evans et al. 1998). Highly populated households have been shown to increase marital instability and result in the more frequent disciplining of children (Fuller et al. 1993). Previous research has also noted that the impacts of overcrowding on individuals often vary among different subgroups. High-density homes with mothers, children, or low-status individuals are more likely to be problematic compared to other subgroups, and they tend to report more health complaints than other subgroups (Baldassare 1981). All the above effects of high population density on individuals are considered “largely mediated by psychological stress” (Fuller et al. 1993, p. 410). Individuals, however, are not only passively affected by the condition of crowdedness, they can also be adaptive to the social context. Residential overcrowding has been considered a well-known feature of the immigrant experience in the United States, especially in Southern California. Researchers find such an overcrowding situation has been reduced due to the growth of immigrants' incomes, although patterns of decline in overcrowding vary significantly among different racial groups (Myers and Lee 1996). This phenomenon provides an example of how individuals improve the situation of overcrowdedness.

Even though psychological stress is treated as the major mediator shaping the manner in which crowding impacts individuals, other factors have been found to play a role through interaction with psychological pressures. These factors include social support for children and parents, gender, and interactions among individuals. Social support is important because individuals in crowded families are often associated with deteriorating social support structures, which may intensify an individual's psychological pressure (Evans et al. 1998). Gender is often related to the level of stress and an individual's behavior. It has been found that stress is more marked among males than among females in high-density locations (Evans et al. 1998; Freedman et al. 1972; Paulus 1988). Moreover
interaction among household members tends to determine the way individuals handle psychological stress (Evans et al. 1998). Thus providing social support for crowded families, especially for males, and strengthening parent-child interaction and family members’ communication may reconcile the problems in overcrowded households.

At the societal level many countries and places with rapid population growth rates and high population densities have developed a number of strategies to slow down their population growth. China, the country with the largest population in the world (almost 1.3 billion people in 2005) has made considerable efforts to reduce its fertility and control its population growth. These efforts include the “later, longer, and fewer” policy (later marriage, longer intervals between births, and fewer children) in the early 1970s (Qian 1983) and the nationwide one-child policy announced in 1979. Consequently, along with social and economic developments, China has experienced a remarkable decline in fertility since the 1970s (Poston 2000), and this has led to considerable population control in China. These programs, however, have also raised demographic and social concerns. One of them is the unbalanced sex ratio at birth (SRB) in China. Due to the strong tradition of son preference and the policy constraints of one birth per couple, the selective abortion of female fetuses and the underreporting of female babies have led to extremely high SRBs in China since the 1980s (Zeng et al. 1993); that is, there are more boys born every year than girls. It is estimated that between the years of 2000 and 2025, there will be more than 31.6 million marriage-age Chinese males who will not be able find Chinese brides. There will not be enough Chinese women in the marriage market for them to marry. These “bare branches” may possibly result in increases in sexual crimes owing to forced marriages, girls stolen for wives, bigamy, prostitution, rape, and adultery (Posston and Zhang 2007). The surplus boys could eventually threaten national stability and international security. Thus it is crucial to strategically coordinate the population growth rate, resources, and social and economic development.

PO POPULATION STUDIES

Population studies is broadly defined as the scientific study of human populations. Major areas studied include broad population dynamics; fertility and family dynamics; health, aging, and mortality; and human capital and labor markets. Researchers in population studies also focus on methodology. Population studies is an interdisciplinary area of study; scholars from demography, epidemiology, sociology, economics, anthropology, and various other disciplines study populations. Various associations and centers exist throughout the United States and elsewhere. The The population Association of America, established in 1930, is a scientific, professional organization established to promote the improvement, advancement, and progress through research of problems related to human populations. Many university-based population studies centers are located throughout the United States, such as the University of Michigan’s Population Studies Center and the University of North Carolina at Chapel Hill’s Carolina Population Center.

PO POPULATION DYNAMICS

Among population researchers, demographers are concerned with the empirical study of population dynamics; that is, demographers study population determinants and consequences including size, composition, how populations change over time, and the processes influencing those changes. Demographers deal with the collection, presentation, and analysis of data relating to the basic lifecycle events and experiences of people: birth, marriage, divorce, household and family formation, migration, employment, aging, and death. They also examine compositions of populations by sex, age, race, ethnicity, occupation, education, religion, marital status, and living arrangements. Demographers further assess the distribution of populations by region, country, province or state, urban or rural area, and by neighborhood. Most demographic data come from population censuses, vital registration systems, national registers, and surveys.

Demographers use a variety of counts, rates, ratios, and other statistics to measure fertility, mortality, migration, and other population dynamics. The crude birth rate is the annual number of live births per thousand people; the general fertility rate is the annual number of live births per thousand women of childbearing age. The crude death rate is the total number of deaths per thousand people; the mortality rate is the number of deaths in some population, scaled to the size of that population, per unit of time. The morbidity rate refers to the number of people who have a disease compared to the total number of people in a population. The infant mortality rate is the annual number of deaths of children less than one year old per thousand live births. Life expectancy is defined as the number of years that an individual at a given age can expect to live at present mortality levels. For example, in 2001 the average life expectancy at birth in the United States was seventy-seven years.

The crude death rate, applied to a whole population, can be misleading. For example, the number of deaths per thousand people can be higher for developed nations than for less-developed countries, despite standards of health being better in developed countries. This is because developed countries have relatively older people, who are more likely to die in a given year, so that the overall mortality rate can be higher even if the mortality rate at any given age is lower. A more complete picture of mortality and life expectancy is given by a life table that summarizes mortality separately at each age. A life table is a table that shows, for a given person at a given age, what the probability is that the person dies before his or her next birthday. Life tables are usually constructed separately for men and for women because of their different mortality rates. Other characteristics can also be used to distinguish different risks, such as health behaviors and socioeconomic position.

As the world population doubled from three to six billion, researchers in population studies have been examining shifts in population dynamics. The first five years of the twenty-first century saw a decline in the overall volume of population growth, with the world’s population increasing at a rate of about seventy-six million people per year as of 2005. Overpopulation occurs when the population of a living species exceeds the carrying capacity of its ecological niche. At the end of the eighteenth century, economist Thomas Malthus (1766–1834) concluded that, if unchecked, populations would be subject to exponential growth. He feared that population growth would surpass growth in food production, leading to ever increasing famine and poverty. On a global scale, however, food production has grown faster than population. Moreover, contrary to Malthus’s predictions, natural population growth in most developed countries has diminished to close to zero, without being held in check by famine or lack of resources. This pattern of population growth, with slow (or no) growth in preindustrial societies, followed by fast growth as the society develops and industrializes, followed by slow growth again as it becomes more affluent, is known as a demographic transi-
tion. Benjamin Gompertz’s (1779–1865) law of mortality, a demographic model published in 1825, is a refinement of Malthus’s demographic model.

Future population growth is difficult to predict. Birth rates are declining on average, but vary greatly between developed countries (where birth rates are often at or below replacement levels) and developing countries. Death rates can change unexpectedly due to disease, wars and catastrophes, or advances in medicine. Population pyramids, graphs that display a population’s age and sex composition, are often used to provide information about future population growth or decline.

Researchers in population studies are also interested in the impact of migration on population dynamics. Migration is the geographic movement of people across a specified boundary. For instance, in the United States, suburban areas are growing more rapidly than central cities. Immigration refers to moves between countries. Immigration is one of the defining characteristics of twentieth-century America; one of the most important changes for the U.S. Census 2000 was the revision of the questions on race and Hispanic origin to better reflect the country’s growing diversity.

FERTILITY AND FAMILY DYNAMICS
Population researchers are interested in various facets of family dynamics, cohabitation, marriage, childbearing, and divorce, trends in these dynamics, and differentials in fertility and family dynamics by race, ethnicity, education, and income. Fertility, the number of births for an individual or population, is distinguished from fecundity, the physiological ability of individuals or couples to have children. While the theoretical maximum is estimated to be about fifteen children per woman, even in the world’s highest fertility countries the average has rarely exceeded eight. The average fertility rate for the United States in 2003 was 2.0, and the average for the world was 2.8.

Demographers are interested in how various factors influence the probability that a woman bears a child; Kingsley Davis (1908–1997) and Judith Blake (1926–1993) in the 1950s and John Bongaarts in the 1980s identified “proximate determinates of fertility.” The primary trends of the second demographic transition include delays in fertility and marriage; increases in cohabitation, divorce, and nonmarital childbearing; and increases in maternal employment. Women also vary considerably in when and how many children they will have depending upon age, race, income, religion, and many other social, economic, and cultural factors.

HEALTH, AGING, AND MORTALITY
Epidemiologists, population researchers who study the distribution and determinants of disease frequency, aim to identify factors that promote health and reduce the burden of disease in human populations. A disease is broadly defined as an abnormal condition of the body or mind that causes discomfort, dysfunction, or distress to the afflicted person. Some diseases are infectious, such as influenza, and can be transmitted by a variety of mechanisms. Other diseases, such as cancer and heart disease, are noninfectious or chronic. Aging is generally characterized by the declining ability to respond to stress, increasing homeostatic imbalance, and increased risk of disease. Death is the ultimate consequence of aging. Key areas of research in aging include: demographic trends; health, disease, and disability; labor force participation and retirement; and family status.

Health researchers employ a range of study designs, often integrating molecular, cellular, medical, and social factors such as education to outcomes like disease, well-being, and other health indicators. Morbidity and mortality rates vary by common social categories such as age, sex, socioeconomic status, and race/ethnicity. Research on social class differentials in mortality has a long history. Higher-status individuals live healthier and longer lives than their lower-status counterparts in virtually every society. Despite improvements in public health in the last half-century, large disparities continue to persist between and within countries for a range of health indicators.

HUMAN CAPITAL AND LABOR MARKETS
Sociologists and economists in the field of population studies often examine labor markets and human capital such as education and skills. Researchers examine trends and inequalities in educational attainment. Other areas of study include labor force participation rates, how labor markets operate (including the matching of employees to jobs and differences across labor market segments), earnings differences, mobility, and inequalities by various demographic characteristics. Researchers also examine labor market trends, such as unemployment rates, as well as trends in length of employment relationships. There is a large amount of research on sex, race, and socioeconomic disparities in human capital and labor markets.

POPULISM

Populism, as both ideology and political movement, is nearly a universal, albeit sporadic, feature of all modern democratic political systems. One basic problem in identifying and assessing populist movements can be traced to definitional questions because their basic features are similar to those found in conventional democratic politics. For example, references to “the people” by charismatic leaders who emphasize the need for a “redeeming break” with current practice and who exploit the anger of citizens are all features of populist protest as well as staples of electoral practice. Further, the causes of populist movements are quite varied and can include a wide range of both economic and cultural issues.

In the United States after the Civil War, farmers protested against the impact of industrialization, particularly in regard to railroad rates for their crops, the cost of new machinery, and bank lending policies. These complaints coalesced into a mass movement led by the Farmers’ Alliance. Populists formed their own political party in 1892 and approved a platform that expanded on these initial protests. The party later merged with the Democrats and the movement declined in part as a result of the defeat of William Jennings Bryan by William McKinley in the 1896 presidential election. Populist movements in somewhat different forms, however, continue to reemerge as a factor in American politics. While populism is possibly the only example of an indigenous radical mass movement in the United States, it is a subject of controversy among democratic theorists.

The Farmers’ Alliance was a complex collection of state and local organizations, including two broad groups in the Midwest and the South, that sometimes competed with one another. Since the Southern Alliance did not admit African Americans, these farmers formed their own organization (Colored Farmers’ Alliance). These groups used a variety of inventive measures to increase the price of crops. The price of cotton, for example, had declined below the cost of production. Cooperative trade agreements were made with merchants for lower prices for equipment and higher prices for produce. In some states, the alliance built its own mills for crops. Speakers and lobbyists were hired to publicize the farmers’ plight. The Colored Farmers’ Alliance created aid programs for needy farmers.

Differences in strategies and tactics, however, plagued the movement. Some Texas “alliancemen” favored the policies of Andrew Dunlap, who emphasized a “strictly business” approach of self-help, while others, including S. O. Dawes and Charles William Macune, sought broader goals and focused on reforming the currency system, which they had concluded was the core cause of the farmers’ plight. There were also disputes between relatively economically secure farmers who could afford the “cash and carry” agreements of the cooperatives and indebted farmers who could not.

The goals of the movement began to expand in the late 1880s as the impact of these cooperative plans proved to be more limited than hoped and farmers became disenchanted with politicians who failed effectively to promote agendas that helped elect them to office. Mary Lease, a Kansas activist, allegedly urged farmers to “raise less corn and more hell.” Independent candidates with alliance support ran with considerable success in midwestern states in 1890. In the South, the alliance focused upon taking over the Democratic Party. While these local efforts produced elected officials such as Tom Watson of Georgia and “Sockless” Jerry Simpson of Kansas, who would become major figures in the populist movement, the alliance leaders increasingly came to the conclusion that a national third party was the only hope for farmers.

After series of meetings in Ocala, Florida; Saint Louis, Missouri; and Cincinnati, Ohio, a national convention was held in Omaha, Nebraska, to form a new political party. The Omaha platform itself became a revered document among Populists who regarded it as a “second Declaration of Independence.” The preamble, written by Ignatius Donnelly, announced that “a vast conspiracy against mankind” was about to take “possession of the world.” “If not met and overthrown at once … terrible social convulsions, a destruction of civilization, or the
establishment of an absolute despotism” was certain to follow. The proposals themselves were organized into three categories: finance, transportation, and land. The new party demanded the “free and unlimited coinage of silver and gold,” an increase in the money supply, a graduate income tax, limits on state and federal spending, postal savings banks, public ownership of railroads, privatization of land now held by corporations “in excess of their actual needs,” and reclamation of land owned by aliens. The convention also approved an “expression of sentiments,” including support for a strike led by the Knights of Labor against clothing manufacturers in Rochester, New York, and urged a boycott of the firm’s products. Specific endorsement of a subtreasury plan that provided for government-backed credits for farmers, which Macune had long supported, did not appear in the final document. Nor was a proposal for female suffrage included on the platform, although it had been endorsed at the Saint Louis meeting.

Delegates would likely have nominated Leonidas L. Polk, head of the National Farmers’ Alliance and renowned orator, for president, but they turned instead to James B. Weaver, a former Union general, after Polk’s sudden death. James G. Field, a former Confederate general, was nominated to give the ticket regional balance. Weaver campaigned widely and attempted to trace the ideology of the party back to Andrew Jackson. “The whole movement,” he said, “can be summed up in one sentence: ‘Equal rights for all and special privileges to none.’” The Populist Party received a million votes and twenty-two electoral votes in the 1892 presidential election. Populist candidates at the state level did quite well, although the party was unable to win control of any state government without Democratic Party support.

Several decisions proved to be crucial to the course of populism after the 1892 election. Grover Cleveland’s victory as president was the result in large part of the Populist Party, which drew Republican votes, particularly in western states. The Democrats were severely weakened by the panic of 1894. Some Populists, called “fusionists,” argued that they should now attempt to take control of the Democratic Party away from its conservative leaders. Others argued for a continuation of a separate third party, and others believed that a regionally based party should be the focus of the next elections. When Democrats nominated William Jennings Bryan with Populist support at the Democratic convention in Chicago in 1896, Populists feared that two presidential candidates supporting populist proposals would assure a Republican victory. Some Populists now argued that the new party should endorse Bryan rather than nominate him as their candidate. At their convention in Saint Louis, Populist delegates nominated Bryan but refused to accept his running mate, Arthur Sewall, a conservative shipbuilder, and nominated Tom Watson instead. Populists did not anticipate that the outcome of the election would be a major national party realignment that made Republicans the dominant party for the next thirty-six years. Antifusionists claimed that Bryan’s defeat was largely the result of his emphasis of monetary issues over other Populist ideas. The majority of Populists again nominated Bryan, although a faction of the party dissented and nominated their own candidates. Tom Watson ran as the presidential candidate of the Populist Party in 1904 and 1908 but received only 120,000 and 30,000 votes, respectively.

Despite the collapse of the movement, the themes of the Populist Party have sporadically remerged in American politics. Antipathy to elites, an interest in monetary plans as a fulcrum for political change, support for rural and small-town values, and acceptance of conspiratorial theories are featured in whole or in part among those who supported Senator Joe McCarthy in the 1950s and the presidential campaigns of George Wallace (1968) and Ross Perot (1992) as third-party candidates. Several presidents, including Franklin Roosevelt in 1936, Jimmy Carter in 1976, and George W. Bush in 2004, have employed some populist themes.

The “golden age of populism” in Latin America occurred later than in the United States. These movements were responses in part to the Great Depression. They grew in the context of unstable regimes, and some were more successful than their earlier North American counterparts. The exemplar was Juan Perón, who governed Argentina for two terms as president (1946–1955; 1973–74) with the support of urban workers (derisively called the “shirtless ones” by his opponents) through the promise of numerous economic benefits, the nationalization of major corporations, and the incorporation of trade unions into the government. Perón called his programs the “third way,” but Peronism was in fact a volatile mixture of right- and left-wing elements. Gertúlio Vargas in Brazil and Lázaro Cárdenas in Mexico pursued some of the same policies. Vargas was an admirer of Mussolini, and Perón welcomed fascists to his country after World War II, while Cárdenas invited Leon Trotsky to Mexico after his exile. While those sympathetic to the Peronistas are still a political force and Cárdenas’s regime gave birth to the Party of the Mexican Revolution, or PRM, the current rise of populism can be directly traced to reaction against the “neoliberal” policies of political leaders in the 1990s. Hugo Chavez in Venezuela and Evo Morales in Bolivia, among others, have rejected programs encouraging foreign investment and privatizing social services as policies of U.S. imperialism. Chavez’s “Bolivarian Revolution” emphasizes redistributive programs based on state oil revenues, and Morales promotes the economic and cultural goals of indigenous farmers. Both frame their policies as correctives to the power of local elites and foreign economic interests.
Many scholars locate the basic features of populism in the rise of fascist regimes in Europe and thus conclude that populist appeals are a significant threat to democratic regimes. On the other hand, political leaders such as David Lloyd George in the United Kingdom and Leon Blum in France employed populist themes and programs within a democratic context. Recent populist movements reveal the same range of alternatives. Protests against immigration and economic centralization have produced populist challenges in the Netherlands, Slovakia, Austria, and France.

Scholars are divided over whether populist outbursts represent a desirable form of democratic protest against economic and political centralization or whether they pose a threat to democracy in their emphasis on the authority of the “people” and opposition to economic change.

Positive psychology

During the first half of the twentieth century, psychologists who held either a behaviorist or psychoanalytic perspective were the dominant forces in American psychology. Apprehensive about what they considered the passive view of human functioning that behaviorism represented, and dissatisfied with the focus on abnormality that characterized psychoanalytic interests, a third group of psychologists called for attention to inner experience, internal processes, adaptive functioning, positive life-influences, and self-constructs. The writings of these theorists caught the attention of scholars and researchers and, during the 1950s, the humanistic movement was born. The most powerful voice in the new movement was that of Abraham Maslow (1908–1970), who proposed a dynamic theory of motivation in which internal and intrinsic motivating forces and affective processes lead to personal, social, and psychological well-being. This was a view of human functioning in which subjective experiences and positive attitudes played a prominent role.

Although widespread, the influence of humanistic psychology was erratic. The emphasis on self-processes encouraged a personal and cultural self-absorption that minimized the importance of collective well-being. Moreover, the gap from theory to practice proved difficult to breach, and many laudable but misguided efforts to nurture the self-esteem of individuals fell prey to excesses and, ultimately, ridicule. The goal of focusing on and fostering positive self-perceptions became mired in controversies over the value of self-processes in areas such as education, controversies that continue unabated to this day. Because research efforts were unsystematic and results highly inconsistent, the tenets of humanistic psychology failed to develop an empirical base. As a consequence, the humanistic movement waned during the 1980s as psychologists shifted their interest to cognitive processes and information-processing views of human functioning.

As the twenty-first century arrived, however, there was another vigorous call within the discipline for a science of psychology grounded on positive experience. This positive psychology has been described as the study of human strengths and optimal functioning, and one of its key aims is to foster research on the positive personal traits and dispositions that are thought to contribute to subjective well-being and psychological health. Such research stands in contrast to the traditional study of people’s distress, pathology, and maladaptive functioning that conin-
ues to characterize American psychology. Moreover, although positive psychology shares with the humanistic movement the aim of advancing human fulfillment, one of positive psychology's key aims is that its methodology be firmly grounded in systemic and scientific inquiry.

The central feature of positive psychology is its dual focus on fostering wellness and preventing maladies such as depression, substance abuse, or mental disorders in individuals who are genetically vulnerable or whose problems are exacerbated by the pressures of our modern lifestyles. In education, proponents of a positive psychology call for the powerful need to prevent bullying and other school violence and to foster academic motivation.

What differentiates the approach of positive psychology from that which has characterized mainstream psychology during the last century is the abandonment of the “disease model” of human functioning in favor of a “human strengths model.” The disease model, positive psychologists observe, evolved from the psychoanalytic practice of deducing normality, mental health, and well-being from the study of abnormal individuals, a method that came to dominate the discipline of psychology. In addition, psychologists have been traditionally trained to correct problems rather than prevent them. A human strengths model shifts psychologists' perspective from this focus on mental illness to one on mental health. Thus, prevention is viewed with equal import as correction, and the development of wellness is put on the same footing as the curing of illness. Positive psychologists working in clinical practice would focus on augmenting the strengths of their clients rather than simply correcting and repairing their weaknesses. Those who work in education would have it as their aim to help create healthy school and classroom climates that foster academic success and personal well-being. All professionals who practice a positive psychology would see it as their mission to make individuals stronger and more productive so that they can more easily maximize their own potential.

Because positive psychology promulgates a perspective focused on building competence, not on correcting weakness, proponents call for a focus on the human strengths that act as buffers against mental maladies. These include optimism, happiness, well-being, empathy, courage, friendship, faith, hope, love, honesty, self-determination, autonomy, insight, future mindedness, positive illusions, perseverance, physical health, wisdom, creativity, altruism, and flow. In each case, the aim of positive psychologists is to investigate how these constructs can foster positive human development. For example, those who emphasize the study of happiness are proponents of an evolutionary psychology in which improving that human quality can be accomplished by remaining in closer proximity or maintaining greater emotional close-ness to existing kin, developing deep friendships, reducing subjective distress, managing competitive mechanisms, and exploiting knowledge of evolved desires. Other psychologists suggest that human development and potential can be fostered through the cultivation of an optimistic life view in which the causes of life's events are interpreted in adaptive and beneficial ways.

The American Psychological Association (APA) has itself embraced this approach toward the study of optimal human functioning, making the first issue of the American Psychologist in the year 2000 a theme issue on positive psychology constructs. The APA has also joined with the John Templeton Foundation to create a new award designed to promote the advancement of the new science. The annual award provides the largest monetary prize ever given in the field of psychology.

In the area of education, researchers hope that insights available from investigations that emphasize a positive psychology will alter the present focus of drawing inferences about adaptive functioning from students who are “at-risk” or “unmotivated” to those who are resilient and resourceful. For example, positive psychology seeks to shift the emphasis from research frequently conducted on concepts such as learned helplessness and anxiety to the study of learned optimism and self-efficacy. To these ends, the new researchers urge that positive psychology constructs be integrated with those of traditional and established bodies of educational literature and lines of inquiry.

POSITIVE SOCIAL SCIENCE
The words positive, positivism, positive science, and positive social science have meant many different things to many different people. In the context of French social thought, the words positive science were first uttered, it seems, by Madame de Staël (1766–1817), the eccentric thinker, writer, socialite, and associate of Romantic and scientific utopians of the late eighteenth and early nineteenth century (Gordon 1991, p. 271). Like others in her circle, Madame de Staël was enthusiastic about the role that scientific method could play in advancing human progress toward the goals of spiritual and material perfection. Historians of ideas typically end their trace of positive social science with the originators of modern sociology, that is, with Henri Saint Simon (1760–1825) and his disciple, Auguste Comte (1798–1857). Thus the linguistic turn from positive science to positive social science. There is of course some controversy over the “origins of sociology” question—for example, a case can be made for the claim that Aristotle (384–322 BCE) was the founder of sociology (and, for that matter, of economics, too)—but these claims are not a concern here.

Still, historically and methodologically speaking, positive social science is a difficult notion to define precisely. One way to define it is to name what its diverse advocates claim it is not: positive social science is not old school metaphysics, and it is not a normative branch of science, such as welfare economics or applied ethics. Against the speculative metaphysics of Plato (427–347 BCE) and Immanuel Kant (1724–1804), for example, and against the value judgments of moralists such as Jean-Jacques Rousseau (1712–1778) and Comte and the contemporary philosopher John Rawls (1921–2002), positive social scientists are united in their attempt to understand and explain the sensory world in objective, logical, factual, and value-neutral observational terms. The positive social scientist seeks a view from nowhere, or from God’s eyes. He does not necessarily do the empirical, factual side of the homework on his subject; he need only claim to believe that his logic speaks to the factual and logical as ultimate arbiters of objective inquiry. Since the late nineteenth century, most adherents to positive social science have dropped the historical belief in “progress” toward “perfection” by discontinuous stages or constant evolution, the inheritance of Comte and de Staël. After the publication of Grammar of Science (1892) by Karl Pearson (1857–1936), and especially after the 1929 publication of Wissenschaftliche Weltanschauung: Der Wiener Kreis (A Scientific Conception of the World: The Vienna Circle), the manifesto of the so-called Vienna Circle, the aims of positive social science entailed a set of beliefs and an argumentative style more than it did a historical explanation or perfectionist state to be aimed for.

If positive social science ever had a firm philosophical grounding, the grounding was provided not by the so-called wertfrei (value-free) social science of the economic sociologist Max Weber (1864–1920) but rather by a series of philosophical arguments commonly referred to as logical positivism. Initially a loosely knit group of philosophers, physicists, economists, sociologists, and mathematicians, the logical positivists were directly associated with or otherwise allied with the Vienna Circle. A goal of the logical positivists, early and late, was to firmly lodge the “fact/value dichotomy” into the minds of working scientists, a dichotomy first brought to the attention of philosophers by Kant and to social scientists by David Hume (1711–1776). Logical positivists tended to confine the analytic/synthetic argument of Kant with the ought/is argument of Hume. Despite or perhaps because of their struggle to construct a “unified science,” the positivists did not much quibble over their own ambiguities.

Ever since a simple faith in positivism has faded, social scientists have typically stuck to a Humanist argument. Hume, many interpreters have said, suggests in Book III, Part 1, of his Treatise of Human Nature (1739) that one cannot derive ought propositions from is propositions. He is commonly understood to have argued that value judgments cannot be derived from factual observations. Facts and values are distinct entities, most of his interpreters have held, making a kind of fork between data and judgment. Since the 1920s the vast majority of economists, political scientists, and psychologists have taken Hume’s fork as dogma. A similar influence of the fact/value dichotomy on medical and biological research has not gone unnoticed (by contrast, anthropologists and sociologists have long raised objections to it).

Logical positivists took Hume’s fork to be the whole scientific meal, a belief that rapidly entered the mainstream of social scientific thought. Only scientific statements were to be accepted as “cognitively meaningful.” And only axiomatic and value-neutral statements about the facts of the world would count as science. Value judgments—especially judgments of an ethical kind—were said to be the province of preachers and poets, objectively speaking, ‘meaningless,’ no guide to social or economic policy.

Often it is not obvious how one can push values entirely aside so that objective facts are the only entities revealed. Take, for example, the sentence “Iraq does not have weapons of mass destruction.” At one level of reading, it is a straightforward factual claim—true, false, or uncertain. Iraq is a nation, nations engage in both self-defense and aggressive war, weapons of mass destruction have been used in war by other nations, and many nations
agree on what counts as a weapon of mass destruction: these are facts. Presumably one could assemble a team of social, physical, and life scientists, trained in best-practice census tabulation, sampling theory, and experimental and analytical methods, such that—conditional on Iraqi government cooperation or military force—one could arrive at a correct answer to the central factual claim: Iraq does not have weapons of mass destruction.

But the interdependence of facts and values can be illustrated by a single change in subject-object relation. Suppose the original sentence is changed to “The United States does not have weapons of mass destruction” (a change in subject) or “Iraq does not have balloons for school decoration” (a change in object). Changing the subject from Iraq to “the United States” or the object from weapons of mass destruction to “balloons for school decoration” involves not merely a change in the facts of the subject and object, but a thorough-going change of perspective, driven not by the raw facts—however defined—but by value judgments largely or entirely embodied by the original sentence. Some officials of the U.S. government, including some high-ranking scientists, obviously do not care about, or are not troubled by, the fact that the U.S. government has weapons of mass destruction. “The United States does not have weapons of mass destruction” is not a factual statement that can elicit a similarly massive sacrifice of money, time, capital, and human lives. A change in object brings one to a similar conclusion. “Iraq does not have balloons for school decoration” is a claim that could presumably be answered by the same team of scientists, statisticians, and military personnel. But the U.S. government does not value the answer to the latter claim; it will not sacrifice many resources to discover the truth about balloons.

Fact statements and value statements are interdependent in science because human motives generate the questions and methods of science. This is not a bad thing to admit for either science or society—on the contrary, it is probably an advantage. Free and public deliberation over the values and interests of science and society is, for instance, an alternative to despotism and mass ignorance. And the expansion of free and democratic alternatives tends, social scientists agree, to increase human well-being. Opinions differ on the 2003 U.S.-led invasion of Iraq. For example, some say the loss to the world of being wrong about the original claim may be so large that any scientific and military investigation should receive funding until surety on the issue is achieved. But even then one is not armed with reasons sufficient to justify allegiance to the factual side of the alleged fact/value dichotomy. Different opinions on facts and values prevail over most public matters. For example, many public institutions, from elementary schooling to space exploration, persist with mass approval, despite a wide variance of professional economic opinion. To put it another way, who would spend billions of dollars trying to discover whether another nation has balloons to decorate their schools? Only a fact-crazed scientist, lacking a rhetoric of values.

At still another level of reading—as seen from the values-only side—the fact/value dichotomy remains dubious. Suppose the original sentence is changed to “According to the United States government, Iraq should not have weapons of mass destruction.” The new sentence directly appeals to a value judgment. Notice it does not say exactly from whom the value judgment is coming (only “the government”). And it does not say who the speaker of the sentence is. But the word should has replaced the word does, signaling, it seems, an abandonment of facts and a decisive move over to the values side of things. But there are at least two objections one can raise to such a conclusion: (1) The author of the original sentence and her readers were never on the facts-only side of things, as the argument above suggests, in the first place; and (2) The sentence “According to the United States government, Iraq should not have weapons . . .”, if taken in the same spirit as the supposedly facts-only claim (“Iraq does not have weapons . . .”), must entail a moral commitment to change the situation (that is, the situation implied by the fact that Iraq has the weapons, if they do). But if the U.S. government is to change the situation, as indeed it endeavored to do when it sought to determine factually whether Iraq had the weapons, it must commence with the same or similar scientific investigation and, perhaps, military force, as in the previous case. The decision of a scientist engaged in free inquiry is not a decision to speak about facts as against values, or positive science as against normative science; it is a decision to choose transparency over opacity. Status quo belief induces most to choose the latter. Yet by 1974 one scholar counted “two score and more of [philosopher and scientist] witnesses against the fact-value split” (Booth 1974, p. 207; emphasis added).

The philosopher and logician Hilary Putnam (2002) has taken the argument a step further, showing that even if one insists that is and should or is and ought are radically distinct, and that ought propositions cannot be derived from is propositions, as some scientists maintain in, for example, the case of weapons of mass destruction, there are still further “value judgments” of an aesthetic type that permeate the most factual sounding research claims. (Putnam's observation is not original, but it is nowadays rare: one can find a similar link between aesthetic qualities of science and normative judgment in Aristotle's Rhetoric.) Scientists value, for example, “coherence,” “simplicity,” and “consistency” in their models and facts (and again Putnam is hardly the first scholar to say so; cf. Burke 1950). Aesthetic values are always at play in science and
are, as any scientist who has received a referee report can attest, constantly being judged by "positive" scientists.

It has been a long time since any respectable historian or philosopher of science believed that logical positivism succeeded in its goal to speak in a circumscribed, fact-and-logic only language. Today, very few philosophers adhere to the fact/value dichotomy, though, to repeat, social scientists cling to it.

POSITIVE SOCIAL SCIENCE AND NOVELTY IN ECONOMICS

Still, many novel ideas in economics have emerged despite the strange faith. Before the publication of Milton Friedman's (1912–2006) *Essays in Positive Economics* (1953), the Dutch economist Jan Tinbergen (1903–1994) and the American economist Lawrence Klein were inspired by visions of positive science to build multiequation econometric models of the Dutch and U.S. economies. The facts of these economies could be revealed through logical (that is, model-based) relations widely held by economists. Both models failed at the level of macroprediction. But for their remarkable technical achievements, both Tinbergen and Klein were awarded (in 1969 and 1980, respectively) the Nobel Prize in Economic Sciences.

Following the work on the theory of human capital by the economist and 1992 Nobel laureate Gary S. Becker, first developed in the 1950s and 1960s, positive economists and sociologists have developed new methods for examining the extent of racial and gender discrimination in labor markets. Becker has argued that competition and the pursuit of profit will drive racist and sexist employers out of business. In statistical regression analyses, researchers after Becker have attempted to show the quantitative influence of race and gender by holding constant a host of independent variables—education level, family structure, labor force attachment, and so forth—such that race and gender are the only variables left in the model to "explain" black-white, male-female, or white-male/black-female differences in wages and occupational attainment.

That an adherence to positive social science and the fact/value dichotomy is coincident with some novel ideas in social science research does not demonstrate the fact or value of positive social science, however circumscribed. Indeed, both the Tinbergen-Klein and Becker research programs have been criticized on "value-laden" grounds: new classical and rational-expectations macroeconomists object that Tinbergen's and Klein's Keynesian models of agent behavior are not "consistent" with rational choice theory (consistency being a value judgment), and a wide range of economic sociologists working in the tradition of W. E. B. Du Bois (1868–1963) and St. Clair Drake (1911–1990) reply that Becker's independent variables are themselves the products of racial and gender discrimination (O'Connor et al. 2001), a value judgment masquerading in the econometrics as mere data.

POSITIVISM

There are two uses of the term *positivism* in the social sciences, one derived from sociology, the other from...
Positivism

jurisprudence, especially international law. In sociology, positivism was a broad movement of European thought during the second half of the nineteenth century. The name derives from the fact that thinkers returned to the appreciation of positive facts so as to restore the world of nature, which idealists had reduced to a mere representation of the ego. Positivism placed greater stress on immediate experience and on the data obtained through the senses.

In jurisprudence, positivists emphasize textual analysis, in contrast to naturalists, who take treaties and other texts as a starting point for determining the guiding principles of the day. However, if there is no text and a new or revised rule of customary international law is advocated, naturalists are likely to emphasize the actual consequences of the new practice, while positivists underscore intent or motive. This is the opposite of the situation faced in textual analysis. One could imagine situations in which the claim is made that the text should be ignored in favor of a new customary principle. Where there is a conflict between positive law and customary principles, naturalists argue that the customary law claimed to exist should prevail. However, naturalists are also likely to argue that principles can be used to interpret provisions in such texts as the UN Charter, which would reduce the probability of a conflict with custom.

Positivism flourished in Latin America as nowhere else, not even in France, where it was first developed by Auguste Comte (1798–1857). It met the needs of many Latin American intellectuals who rejected Spanish and Portuguese culture and were trying to prove their independence by adopting French ideas. They considered Catholicism as a tool of Spanish imperialism, which had kept Latin America in a state of amoral, chaotic backwardness. Positivism called for progress, discipline, morality, and freedom from the tyranny of theology. The positivists rebelled against the spiritualist metaphysics shared by deists and Catholics. This rebellion turned them into agnostics and sometimes even into atheists.

ADVENT AND EVOLUTION OF SOCIOLOGICAL POSITIVISM

The sociological use of positivism emerged in France under Comte, evolving from English empiricism, which argued that experience was the only source of human knowledge. The new school of thought held that reality mechanically evolves from inferior forms until it attains consciousness in humans. According to Comte, historical observations on the process of human society show that humans have passed through three stages. First was the theological state, in which nature was mythically conceived and the individual sought the meaning of natural phenomena from supernatural beings. Second came the metaphysical stage, in which nature was conceived of as a result of obscure forces and the individual sought to explain natural phenomena from them. Third came the positive stage, in which all abstract and obscure forces are discarded and natural phenomena are explained by their constant relationships. Comte extended the law of the three stages to include all reality.

Jurisprudential positivism emerged in the nineteenth century and gained influence in the twentieth century because of the tendency to replace customary or natural law with statutory or treaty law. In international law, positivism gained even more influence after the 1945 UN Charter. Positivists argue that the charter, and law generally, should be treated as a constitution that, following the model of H. L. A. Hart (1961), establishes “primary” rules (to make rules) and “secondary” rules based on them that establish particular policies and principles, including, but not requiring, conceptions of justice and other issues of substance. In international law, if treaties are read loosely, or principles are imputed or inflated, or customs are claimed rather than observed, positivists feel that the consent required for law to exist on the basis of explicit rules does not exist. Furthermore, in specific applications, motives matter in order to assure that the community of nations agrees. Because motives are difficult to know, the presumption of positivists is that consent for actions against prevailing interpretations of legal doctrine must be unambiguous for law to deviate from claimed fundamental principles. Opposition to what is clearly the intent of positive law as expressed in texts is normally a sign of illegality.

Sociological positivists did not follow exactly the same course in the Latin American countries. Positivism was most influential in Brazil, whose elites studied French and visited Paris, where they came to admire everything French. By the end of the nineteenth century these elites wanted to import or copy everything they associated with France. At the time, positivism became particularly important in Brazil’s technical schools and military academies, where many middle-class children studied. Comte’s emphasis on progress through gradual change appealed to Brazil’s new elite, who saw positivism as a way of incorporating themselves into the national elite without threatening the social order on which the old elite depended. They were attracted by the idea of using military and government officials to plan economic development for progress and industrialization. They believed that by expanding economic opportunities and education, they could incorporate the disenfranchised into society without the need for widespread social or political change. Furthermore, in positivism they saw the possibility of ending foreign economic domination and colonialism in Brazil.
MAIN PHILOSOPHICAL TENETS OF JURISPRUDENTIAL POSITIVISM

Jurisprudential positivism, following a line of jurisprudence that has included the theories of Vattel, Zouche, Kelsen, and Hart, emphasizes legal rules and consent in the relations of states. Rights and obligations about rules and principles are based primarily on the words in treaties. Based on the empiricism of Locke and Hume, positivists in international law, such as Humphrey, the principal author of the Universal Declaration of Human Rights, Schachter and Henkin among lawyers and Donnelly among political scientists, have argued that rules take precedence over claimed principles or unprecedented customs of states. Without observable experience or consent, validating customs after the fact betrays self-serving, perverse incentives besides nullifying the original intent of primary rules.

Jurisprudential positivists cite three UN Charter articles that make humanitarian intervention presumptively illegal. First, Article 39 of Chapter VII limits coercion sanctioned by the United Nations Security Council (UNSC), whether by the UN or by the armies of member states, in three situations: a “threat to the peace, breach of the peace, or act of aggression.” Taken literally, Article 39 (and the title of Chapter VII) does not apply to a country that is killing its own citizens but not threatening or attacking other countries. Second, positivists might also argue that unilateral humanitarian intervention would usually be illegal because of Article 2(4), except either when the UNSC finds an Article 39 situation, as indicated above, or for individual or collective self-defense to armed attack under Article 51. Article 2(4) names only three situations in which a state may not threaten or use force: (1) against the territorial integrity, or (2) political independence of any state, or (3) in any manner inconsistent with the purposes of the United Nations.

Jurisprudential positivists define a violation of territorial integrity as an armed attack on another state and a violation of political independence as a de facto partition or loss of sovereignty over part of a country. Donnelly calls for “positive non-intervention” to respect UN Charter Article 2(7)’s intervention prohibition and encourage uninhibited criticism. “Nonintervention” means only the renunciation of “intervention,” in the strict sense of coercive interference. International human rights, however, are an appropriate subject for the exercise of international influence. Inaction in the face of human rights violations is not only morally inappropriate, it is in no way required by international law.

Some positivists, such as Schachter, would permit armed humanitarian intervention for great emergencies and with a consensus among the five permanent members of the Security Council. In commenting on UNSC Resolution 688 regarding northern Iraq, he notes that the council could invoke the Chapter VII enforcement procedures, at least if there is some threat to international peace as well. Others, such as Henkin, might be willing to forgo UNSC authorization to authorize force to stop mass murder, but not in the face of a likely veto. Positivists might be divided on whether to insist upon a consistent standard for legal humanitarian intervention or to permit it where it is politically possible. As Henkin (1991, p. 41) suggests, “The Charter does not prohibit humanitarian intervention by use of force strictly limited to what is necessary to save lives.” He would presumably not accept humanitarian intervention if a UNSC consensus was absent or if a unilateral intervention were to change national boundaries or replace a government: “It has not been accepted, however that a state has a right to intervene by force to topple a government or occupy its territory even if that were necessary to terminate atrocities or to liberate detainees.” Henkin also opposes using force to promote democracy, as do his ideological opposites, Franck and the Reagan administration.

POSSIBILITY THEOREM

SEE Arrow Possibility Theorem.

POSTCOLONIALISM

Postcolonialism is a generalized term used to describe the variety of events that have arisen in the aftermath of European decolonization since the nineteenth century. Among the events included under the rubric are social change, cultural redefinition, and political upheaval on both the small and large scale. The term implies a breaking free or a breaking away from a colonizing force, but essentially the study of postcolonialism addresses issues of power, subordination, race, gender inequity, and class—and examines how these issues linger far after the colonizer has exited. It is sometimes understood that colonialism ended in the early to mid-twentieth century, but the vestiges of colonial power and influence remain in many parts of the once colonized world. These vestiges can be seen in the unequal sharing of power in government, especially when Western interests are at stake, as well as in inequities in military control, resource allocation, and economic benefits when more powerful governments and entities participate in economic exchanges with postcolonial nations.

POSTCOLONIAL THEORY

Postcolonial theory has been developed in various fields, including philosophy, literary studies, and sociology. From its beginnings in the 1960s and 1970s, with Frantz Fanon and Edward Said, postcolonial theory has addressed issues such as identity, gender, race, ethnicity, and class. It also examines how once colonized nations develop their own identities and how information among the exploited populations has been produced and used both by the colonized and the colonizers. In literary studies, postcolonial theory addresses the question of how the writing produced by the colonized and by those who colonize them responds to colonial legacies.

Postcolonial theorists can trace much of their initial discourse to Antonio Gramsci, who, in his Prison Notebooks ([1929–1935] 1992), examined the subaltern, or those who were excluded from power by virtue of their race, class, gender, ethnicity, or colonial status; this study was later taken up by Partha Chaterjee (1993), among others. Fanon, in the Wretched of the Earth ([1961] 1963), a work considered a landmark in colonialism studies, expressed clear anticolonialist sentiments in his discussion of the Third World. In a highly influential 1978 book, Edward Said argued that a set of attitudes he dubbed orientalism was a way for the West (here meaning Europe) to differentiate itself from its progenitors. Even though Europe in its modern form was essentially a product of the East, to rationalize its ascent to power it aspired to colonize the East through many means, including the physical and economic. Gayatri Spivak, another significant postcolonial theorist, has, like Chaterjee, focused on the subaltern, though as a gendered category—both in terms of those who are colonized and those who have colonized (1988). Feminist postcolonial theorists have additionally discussed sexuality, gender and diasporic communities, power and globalization, and the idea that the feminine in any capacity or context can be equated with a subaltern position.

To make the above comments more concrete, the remainder of this entry will seek to illustrate many of the issues postcolonial theorists are concerned with through a brief examination of one postcolonial country: Ireland. Ireland was a colony of the English for eight hundred years, but perhaps due to its position as a Western country, is often not understood in the same light as other colonies. Its affluence today (the ‘Celtic Tiger’) also makes it easy to forget that it is less than a century since that independence was gained. Since the turn of the twentieth century, Ireland has moved from being a long-term colony of England to being a postcolonial power on its own. The next section examines how Ireland became a colony, its response to colonization and the plantation system, and how it has developed its national identity in the decades following independence in 1922.

IRELAND

Ireland has been a colonized nation since the time of the Vikings in the ninth century. The Vikings were followed
in 1169 by the Normans (the “Old English”), who began “civilizing” the native Irish. In more recent times, as with many colonized nations, Irish perspectives on the colonial situation varied based on the nature and closeness of economic relationships with the colonizer, and whether those relationships conferred economic advantage. During the plantation era, Anglo-Irish, who had thrown their lot in with the English, could hold lands and resources their Irish brethren were excluded by law from owning. Lower-class Irish were indentured laborers on plantations, though a few could hold small plots of land; Irish who once had held political or social power were striped of their valuables, land, homes, and driven into exile—either to another country or into the poor counties of western Ireland.

The Reformation was brought to Ireland by Oliver Cromwell in 1649. He was not the first Englishman to arrive on Irish shores, but he was among the first to come with arms and the intent of suppressing the Irish people as a class and forcefully instituting Protestantism. In that he was very successful. A brutal military strategist, Cromwell destroyed entire towns and villages, including the walled city of Drogheda, where he burned 3,000 people alive. From then on, Ireland remained under the control of the English. Though a variety of short-lived uprisings and revolts occurred over the centuries, it was not until the Potato Famine of the mid-nineteenth century that the Irish were able to bring their plight to the attention of the rest of the Western world. Millions starved to death, millions more were forced to leave Ireland. In the space of ten years (1846–1856) Ireland’s population halved from eight to four million. The 1916 Easter Uprising, led by Padraig Pearse, loosened the hold the English had over the country. Though principally limited to urban centers such as Dublin and Cork, the Uprising reverberated across the country. When the heroes of the uprising were executed or jailed in the months that followed, civil war broke out. In 1922 Ireland gained independence from England, but was partitioned—most of Ulster would remain under the English flag while the Irish Free State was inaugurated in the south.

Despite their hard-won freedom, Ireland remained closely linked with England and depended on it economically for several decades. During this time, however, following the lead of people like President Eamon de Valera, and poets and authors W. B. Yeats, Brendan Behan, and Patrick Kavanough, the Irish began to consciously express their own national identity through a revival of Gaelic culture. This revival, known as the Celtic Twilight, was based on a vision of Ireland as a rural idyll, in which people were closely tied to the land. With the Celtic Twilight came a revival of the Irish language, which had been on the brink of extinction, and now became part of the school curriculum. This restoration of a national language separate from that of the colonizer is a common response to decolonization. Traditional Irish music was also revived and is now popular throughout the world. The Gaelic Athletic Association, which organizes hurling and Gaelic football and was first established in the 1880s, has steadily risen in popularity as well.

Only recently, beginning in the 1970s, has Ireland truly developed a modern national identity and become an independent economic powerhouse. Since the 1990s, Ireland has been dubbed the “Celtic Tiger,” a reference to its new wealth and status. As of 2006, Ireland has the fourth strongest GDP in the world behind the United States, Norway, and Luxembourg (ESRI 2006). In July 2006 Ireland ranked second among the wealthiest nations in the world behind Japan (RTE 1, 2006).

POSTLETHWAYT, MALACHY
1707–1767

Malachy Postlethwayt was a prolific English writer and publicist on matters of mercantilist economics in the 1740s and 1750s. Little is known about his upbringing or formal education, although he is believed to be the brother of James Postlethwayt (d. 1761), a writer on finance and demography. Malachy Postlethwayt was elected a fellow of the Society of Antiquaries of London in 1734. His writings are claimed by Edgar Johnson to “have exerted a good deal of influence on the trend of British economic thought” (1965, p. 185).

Postlethwayt was alleged to be propagandist for the mercantilist endeavors of the Royal Africa Company, whose interests were well served by his publications The African Trade, the Great Pillar and Supporter of the British Plantation Trade in North America (1745) and The National and Private Advantages of the African Trade Considered (1746). These works supported a strategy of British commercial and manufacturing expansion through trade with Africa and the colonies, and promoted the importance of slavery for British commerce and industry.

Postlethwayt’s most noted work, The Universal Dictionary of Trade and Commerce, appeared after he had devoted twenty years to its preparation. The first edition was published in London in installments between 1751 and 1755, and then in subsequent editions as a two-volume set in 1757, 1766, and 1774. This dictionary was a translation, with large additions and improvements, from Jacques Savary des Bruslons’ Dictionnaire universel de commerce (1723–1730). According to Johnson, Postlethwayt’s dictionary was a “huge storehouse of economic facts, laws and theory” (1965, p. 188), and his departures from the French version reflected his “greater interest in political problems; his more intense economic nationalism; and his exuberant belief in the economic usefulness of experimental philosophy” (p. 402).

In the 1757 edition of the Universal Dictionary, Postlethwayt outlined his vision for the establishment of a British mercantile college to benefit those who intended to work as merchants, or in gathering public revenue, or in merchandizing. He proposed that theoretical training for business should occur in formal academies and involve the study of mercantile computations, foreign exchanges and the intrinsic value of foreign coins, double-entry accounting, languages, geography, and public revenues and related laws. Postlethwayt’s ideas appear to have been influential in developing the statutes and procedures of the Portuguese School of Commerce, established in Lisbon in 1759.

Postlethwayt’s most important contribution to economic literature is regarded by many to be Britain’s Commercial Interest Explained and Improved (1757), in which he outlines his concept of “physical commerce” and the policies England should follow to attain commercial parity with foreign rivals.

Whether Postlethwayt’s writings were his original thoughts and words is a matter for conjecture. Johnson (1965, p. 205) notes that his Universal Dictionary included ideas taken from fifty other past or contemporary writers and that it had scattered throughout it practically all of Richard Cantillon’s Essai sur la nature du commerce en général (Essay on the Nature of Commerce in General, 1755). Although Postlethwayt was alleged widely to be a plagiarist, Peter Groenewegen considers this accusation to be “greatly exaggerated” (2004, p. 1000).

Postlethwayt died suddenly on September 13, 1767, and was buried in the Old Street Churchyard, Clerkenwell, in London.

POSTMODERNISM

Ever since its ideas first took hold in the 1980s, postmodern theory has had a significant influence on the social sciences. At the time, social theory imported certain theoretical concepts from literary criticism, including deconstruction and other discourse-based theories of textual interpretation. It is best, however, to refer to a postmodern “turn” within contemporary social science, because many academics influenced by these intellectual trends abjure the term postmodernism. Nevertheless, many contemporary social scientists acknowledge a debt to deconstructive methods of textual interpretation and to deconstruction’s (or poststructuralism’s) rejection of teleological theories (or “grand narratives”) and the concept of a coherent, fixed human subject.

Judith Butler’s writings on the unstable and “constructed” nature of both sex and gender identities played a crucial role in transmitting postmodern concepts into social theory and the social sciences. Yet Butler herself rejects the term postmodernist, claiming only to deploy deconstructive techniques to better discern the “discursive construction” of identity. Postmodern conceptions of the “hybrid,” “plural,” and “inconstant” nature of “identity” and the concept of a coherent, fixed human subject.

Many people working in these areas reject behavioral, structural, and hermeneutic interpretations of the relationship between individuals, groups, and social structure, favoring instead analyses of the “decentered,” “local,” and “fragmented” nature of social phenomena. Postmodern social theory rejects traditional social science’s goal of discerning causal relationships among social phenomena. It also rejects social science aspirations to discern superior or “parsimonious” interpretations of human behavior. In the postmodern conception, no “readerly” interpretation of a “text” can be more “truthful” than another. In fact some postmodernists refer to the concept of “truth” as “terrorist,” for the “truth” can only defend itself by repressive “exclusion.”

Postmodernism represents both a sensibility in regard to social science research and a normative critique of modernity. According to postmodernism, the Enlightenment’s search for rational understanding that could ameliorate the human condition engendered ideological or false “grand narratives” of history, which are based on “essentialist,” “universal,” and “fixed” conceptions of human nature. Drawing upon Jean-Francois Lyotard’s analysis in The Postmodern Condition (1984), postmodernists reject the Enlightenment’s search for “totalizing” theories that offer “universal” narratives of human motivation and experience. Building on the work of Michel Foucault, postmodern theory claims that these “grand narratives” underpinned the Enlightenment’s efforts to “normalize” human beings through the bureaucratic and repressive institutions of “governance” (e.g., both state and nonstate organizations, such as the asylum and the hospital) that “categorize” human beings.

POSTMODERNISM AND DECONSTRUCTION

According to postmodernists, social theories that claim to “represent” reality fail to comprehend that humans have no unmediated access to “reality.” Human conceptions of reality are, unavoidably, a product of subjective interpretation. Modern media and technology deny people the ability to discern the original author or to distinguish the original from the imitation. In 1936 Walter Benjamin argued that in an age of “mechanical reproduction” it is nearly impossible to distinguish the original from a copy. Following this lead, postmodern theorists such as Jean Baudrillard have contended that reality itself is a simulacrum (a copy of a copy). In a world of corporate image production and virtual realities, one cannot determine what is authentic or inauthentic, real or fake. When computers allow people to “live” in cyberspace, the very concepts of reality, time, and space are contestable and destabilized. Thus attempts to interpret the “essence” or true nature of social phenomena deny the reality that the world is a constantly shifting image.

Postmodern social theory draws heavily upon Jacques Derrida’s and deconstruction’s critique of structuralism. Claude Levi-Strauss’s structural anthropology and Louis Althusser’s structural Marxism (which investigated the structural role that class played within capitalist economics and ideology) dominated French intellectual life in the 1960s. Both of these theorists drew upon the early twentieth-century structural linguistics of Ferdinand Saussure. Saussure held that the meaning of a particular speech or language (la parole) is structured by the underlying structure of grammar (la langue, the structured relationship
between signifier and signified that yields the meaning of a sign). But Derrida in *Marges de la philosophie* (1972) held that the relationship between signifier and signified is inherently unstable. For Derrida, “meaning” includes both identity (what is) and *différance* (what is not). Thus postmodernists argue that any attempt to “fix” meaning will yield repressive attempts to eliminate the ineluctable “other” of human reality.

To avoid eliminating the play of *différance*, postmodern-influenced social science rejects the “binary oppositions” that allegedly ground Western philosophy: subject-object, man-woman, reality-appearance, reason-emotion, and speech-writing. In this view, the very effort of representation and causal analysis excludes and devalues the “inferior” part of the binary term that is traditionally denigrated as being irrational or emotional. This rejection of binary oppositions as repressive and “norming” has had a profound influence on contemporary feminist and critical race theory, which warn against “essentializing” identities of gender and race. These studies of identity focus upon the “socially constructed,” hybrid, and ever-shifting nature of individual and group identity.

Given the absence of a stable referential relation between subject and object, postmodernists argue that social theory should focus upon the way subjects are “constructed” by discourse itself. The postmodern conception of how the subject is a product of language and thought draws heavily upon philosophical traditions deriving from Friedrich Nietzsche. In addition, Martin Heidegger’s critique of Western philosophy’s ineluctable search for a fixed conception of “Being,” and of its attempt to dominate nature in the name of the “human,” informs postmodern analysis. Postmodern social science frequently draws upon Foucault’s conception of power-knowledge discourses to examine how subjects are “produced” by discourse. While Foucault’s earlier “archaeological” work on how *epistemes* (or systems of thought) “norm” and “exclude” has influenced postmodern analysis, it is his later genealogical analysis of power as “productive” and “enabling” (rather than as primarily coercive) that has most influenced postmodernism’s critique of “agency.” As Butler holds, the conception of a coherent, rational, human individual who exercises conscious agency ignores the reality that human identities are continually being reconfigured through performative “self-inscriptions” of dominant norms and discourses.

**LACLAU AND MOUFFE AND “NEW SOCIAL MOVEMENTS”**

Ernesto Laclau and Chantal Mouffe’s *Hegemony and Socialist Strategy* (1985) represents a highly influential poststructuralist critique of the use of “grand narrative” in the social sciences. Rejecting a “determinist” Marxism that drew from the workers’ structural position in production of the teleological necessity of a “revolutionary consciousness,” Laclau and Mouffe asserted the “discursive”—and open—nature of social consciousness. In the determinist Marxist view, both social democracy and authoritarian communism believed that capitalism’s interdependent division of labor would inevitably yield (whether through gradual self-organization or via a revolutionary external agent) a self-emancipating working-class movement for democratic control of the interdependent capitalist mode of production. In contrast to the Marxist tradition, Laclau and Mouffe held that one cannot—and should not—mechanistically determine a subject’s “objective, true consciousness” from the subject’s alleged “structural” position in society. Rather, consciousness itself is discursively produced and represents a contested arena for politics.

In this view, much of the emancipatory impulse for democracy has come from the “new” social movements of racial, gender, and sexual identity. The consciousness of these identity-based groups cannot be deduced from their “objective” social role in society. Thus social theorists had to abandon privileging the “old” movement of the working class and construct a new, plural, and democratic theory that would unite (without homogenizing) the liberatory discourses of the new social movements. Laclau and Mouffe’s work has had a great influence on both social movement theory and postcolonial studies.

**POSTMODERNISM AND ITS CRITICS: THE SEARCH FOR NORMS**

The postmodern turn in social science has generated considerable controversy, some of it finding its way into the mass media. Most visible has been the neoconservative critique that postmodernist analysis dominates the humanities and social sciences, imparting to students a dangerous, nihilist critique of American democracy. Ironically, this critique conflates postmodernism with Marxism, despite postmodernism’s hostility to macrostructural and teleological forms of social analysis, including Marxism. Some left-leaning social theorists concur with the postmodern analysis that the marketing of images and lifestyles partly supplants the production and sale of physical goods in late capitalism. But these analysts of late capitalism (such as the geographer David Harvey and the cultural theorist Frederic Jameson), in contrast to postmodernists, offer macrostructural and analytic explanations for the emergence of these phenomena. They locate the production of images-as-commodities within the global corporate conglomerates of the “infotainment,” media, and publishing industries.

The postmodern rejection of the realist conception that economic and social institutions constrain the choices of individuals has occurred at a time of rapidly
increasing global violence and economic and material inequality, and some critics have pointed out the ironic element in the timing of this development. Postmodernists often explain their critique of fixed, “linear” conceptions of time and space by metaphorical references to chaos theory’s rejection of periodicity and to the finding of quantum mechanics that mass, force, and acceleration cannot be independently determined. This postmodernist rejection of even an “unrepresentative” realist conception of an external reality independent of theoretical interpretation helped engender the “Sokal affair.” Alan Sokal, a physicist (and materialist Marxist) at New York University, submitted a paper to the postmodern journal Social Text in 1996. The article cleverly deployed postmodern concepts while making alleged scientific references that any physics undergraduate could readily deem to be ludicrous. After the essay was published, Sokal revealed that it was a hoax aimed at revealing postmodernism’s ignorance of both science and the nature of material reality. The story made the front page of the New York Times.
